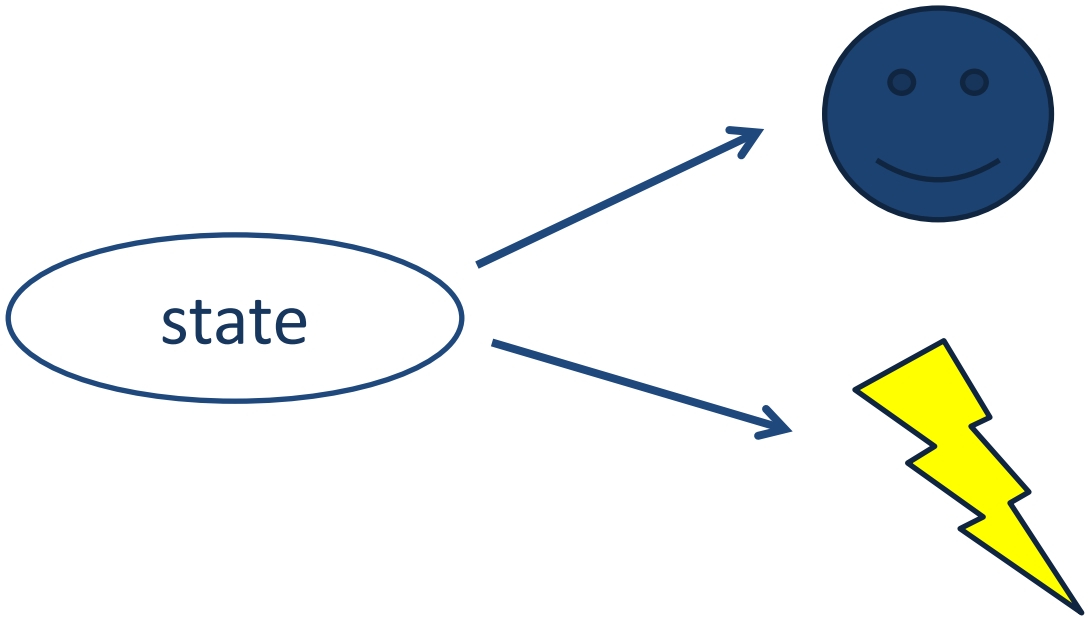
the role of dopamine in planning and action

ON NEURAL CORRELATES OF REINFORCEMENT LEARNING

Reinforcement learning: finding correct action by trial and error



Reinforcement learning
the basics

Supervised learning –

all knowing teacher, detailed feedback

Reinforcement learning –

scalar (correct/incorrect) feedback

Unsupervised learning –

self organization

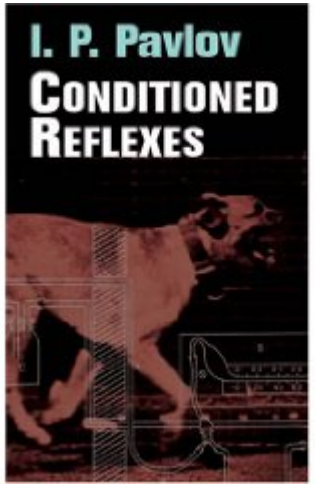
Reinforcement learning: The law of effect

"The Law of Effect is that: Of several responses made to the same situation, those which are accompanied or closely followed by satisfaction to the animal will, other things being equal, be more firmly connected with the situation, so that, when it recurs, they will be more likely to recur"

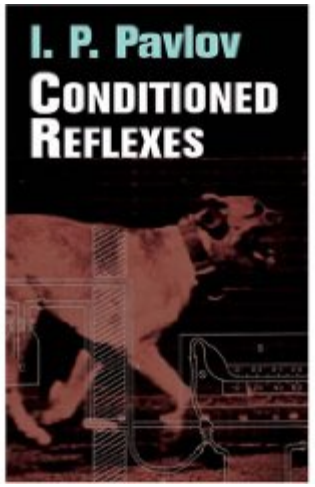
Edward Lee Thorndike (1911)

Early attempts at modeling

- By associative rules
- Classical conditioning



Classical conditioning



The Elements:

US: Unconditioned stimulus

UR: Unconditioned response

NS: Neutral stimulus

CS: Conditioned stimulus

- **CS1**: Conditioned stimulus 1
- **CS2**: Conditioned stimulus 2

CR: Conditioned response

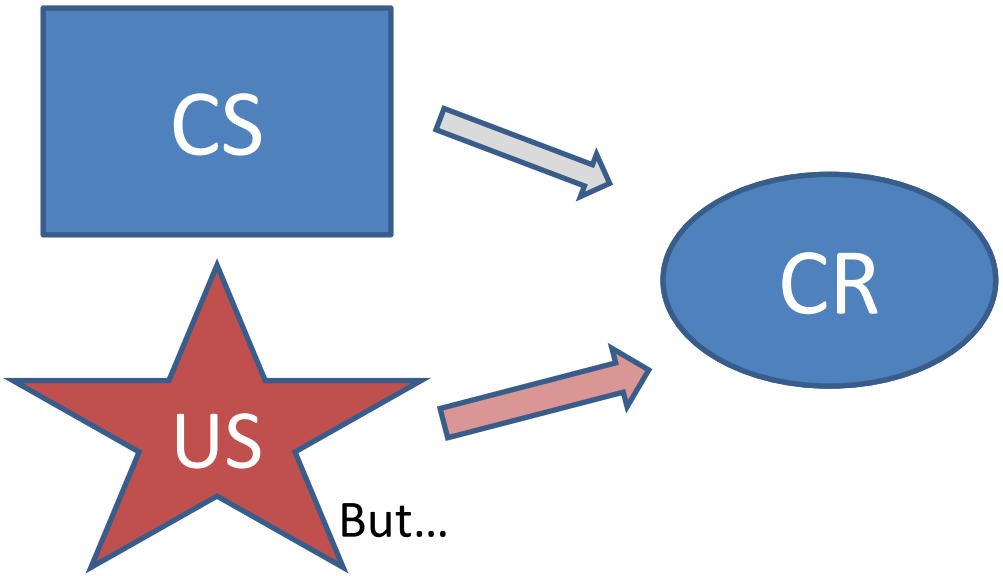
Properties of classical conditioning

(Pavlov 1927)

- **Acquisition**.
- **Partial Reinforcement** (probabilistic).
- **Generalization**.
- **Interstimulus Interval (ISI) effects**.
- **Intertrial Interval (ITI) effects**.

So far…

- A simple association (coincidence, Hebbian) model can explain the phenomenon.



- Acquisition.
- Partial Reinforcemer (probabilistic).
- Generalization.
- Interstimulus Interval (ISI) effects.
- Intertrial Interval (ITI) effects.

Properties of classical conditioning

(Cnt'd)

- **Conditioned Inhibition**
- **Latent Inhibition**
- **Relative validity** (Wagner 1968).
- **Blocking** (Kamin 1968)
- **…**

CS must RELIABLY predict US

Which simple association can’t explain

Learning occurs not because two events co-occur, but because that co-occurrence is otherwise UNPREDICTED

Rescorla-Wagner rule (1972)

Learning to predict reward R given stimulus U=1

Goal: Form a prediction V of the reward of the form:

$V=\omega U$

And learn to change ω :

$\Delta \omega = \varepsilon(R-V)U$

After learning of consistent pairing: ω=R

Where:
U=CS availability (0,1);
V=reward prediction:
R=reward availability (0,1) :
ω = weight of the connection between U and V
ε = learning rate
R-V = prediction error

Blocking with Rescorla Wagner

- Given U1, U2 and R, after U1 has been learnt:
- ω1=R
- V= ω1U1+ ω2U2

R 0

- Prediction error: R-V=0

  And no learning occurs for ω2

The real challenge faced by the nervous system is to select a motor response (to make a decision) that maximizes evolutionary fitness under conditions of uncertainty

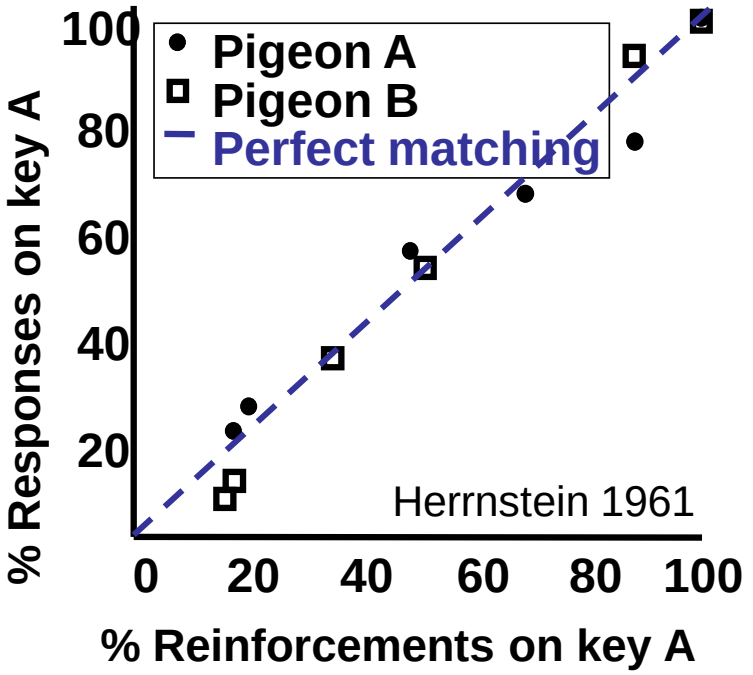
Glimcher, 2004

Matching law (Herrnstein 1961)

In a VI-VI operant reward schedule
The relative response rate *R* matches The relative reward rate *Rf* on that choice

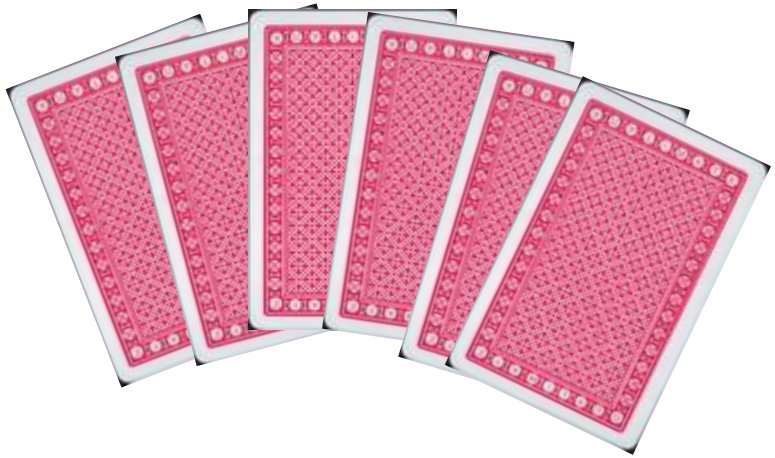
$$\frac{R_1}{R_1 + R_2} = \frac{Rf_1}{Rf_1 + Rf_2}$$

Experimental data



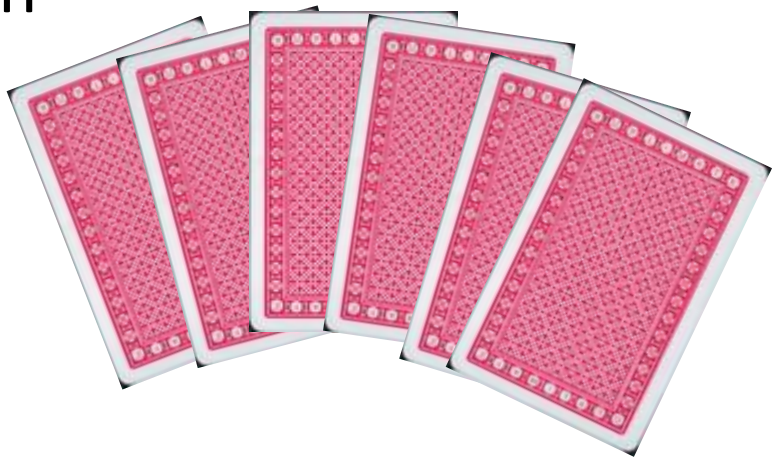
Critical problems, for control

1. Exploration/exploitation

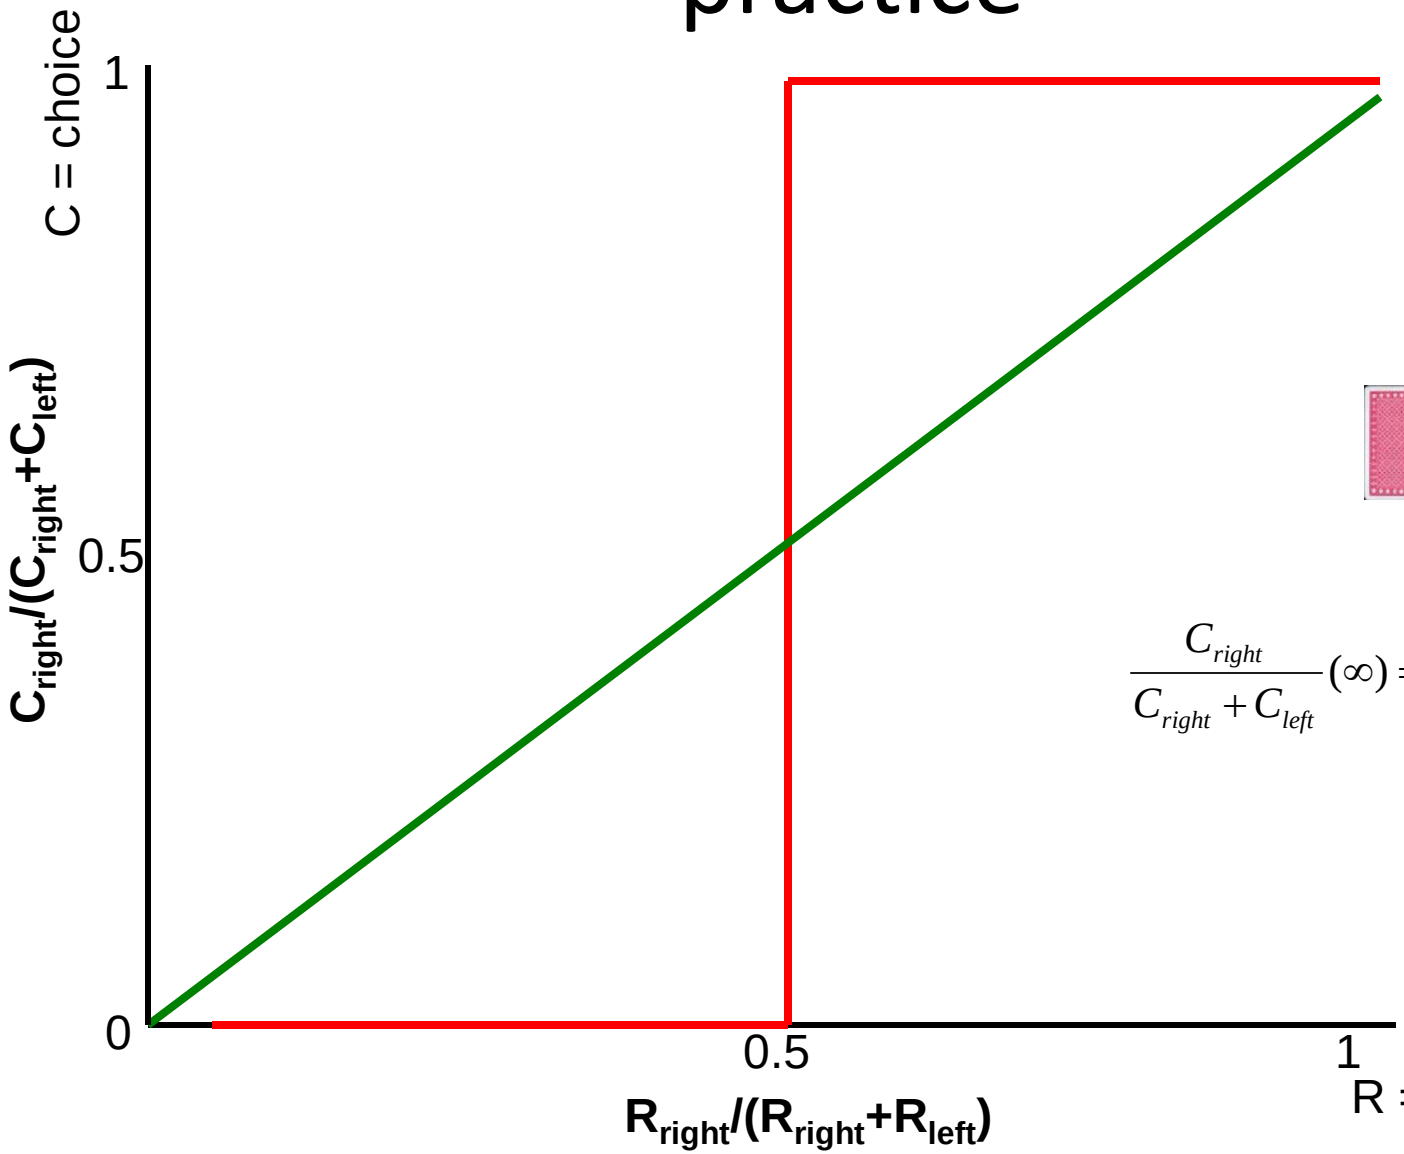


Solutions, for control

1. Variability in response policy
    1. Greedy ← → Random (gambling)
    2. Based on expected return

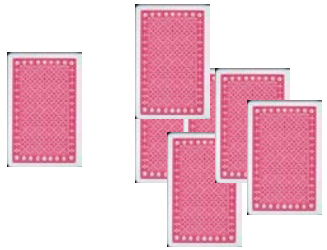


Decision behaviour, theory and practice



maximizing

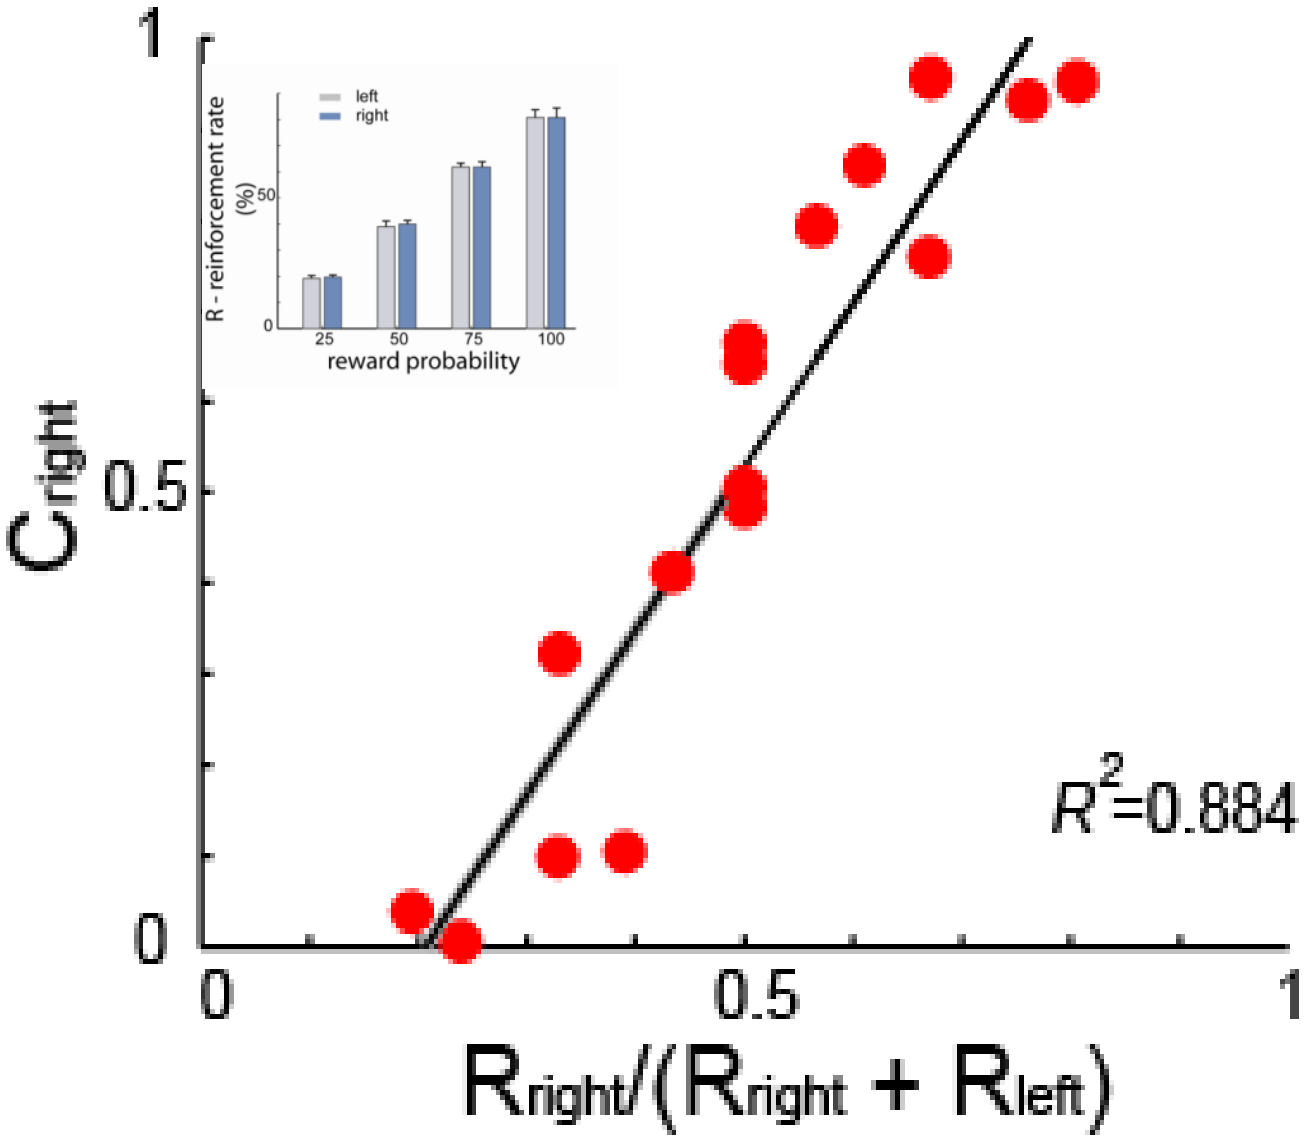
probability-matching



$$\frac{C_{right}}{C_{right}+C_{left}}(\infty)=\frac{R_{right}}{R_{right}+R_{left}\cdot\frac{\theta_{left}}{\theta_{right}}}$$

monkeys?

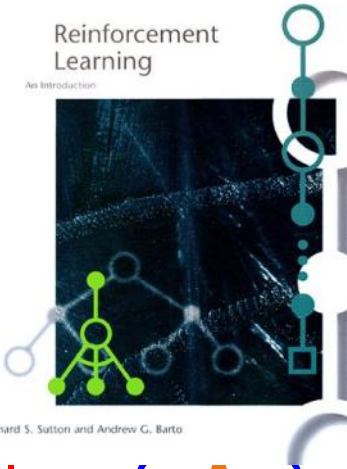
Monkeys' decisions: probability matching



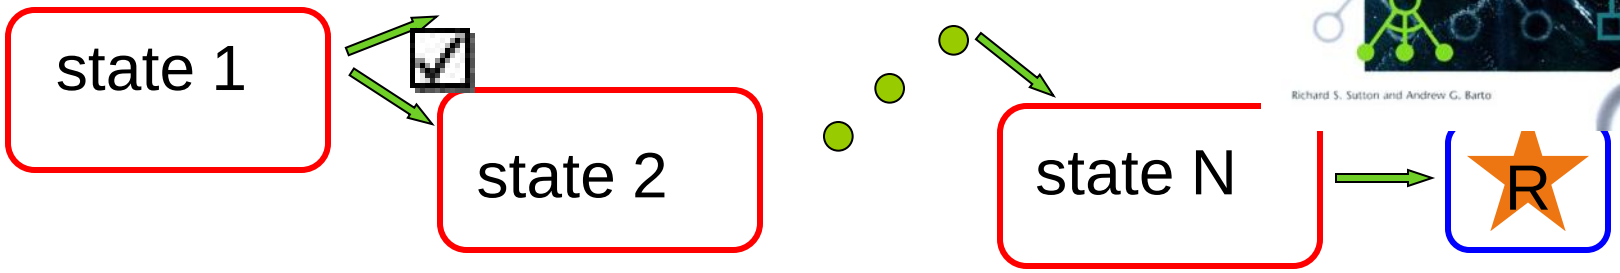
… whether optimal or not

- Actions are related to their consequences

Critical problems in reinforcement learning (and in Rescorla-Wagner)



2. Temporal credit assignment



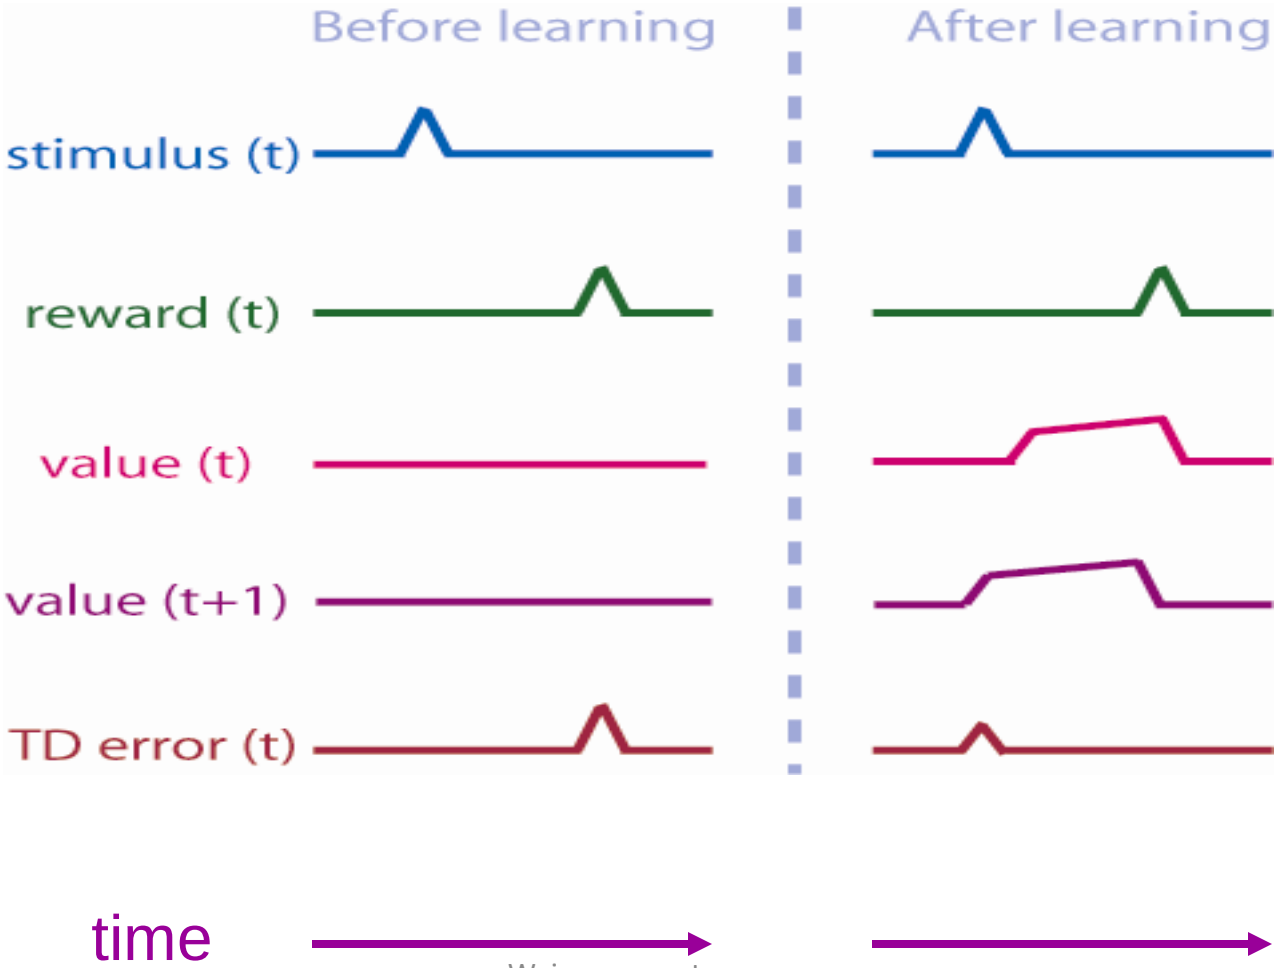
TD learning - solution for temporal credit assignment

1. Estimate value of current state $(V_t = r_t + \gamma' r_{t+1}{}^{+\cdots})$: (discounted) sum of expected rewards
2. Measure 'truer' value of current state: reward at present state + estimated value of next state $(r_t + \gamma V_{t+1})$
3. TD error $\delta_t = r_t + \gamma V_{t+1} - V_t$
4. Use TD error to improve 1 $(V_t^{k+1} = V_t^k + \eta\, \delta_t)$

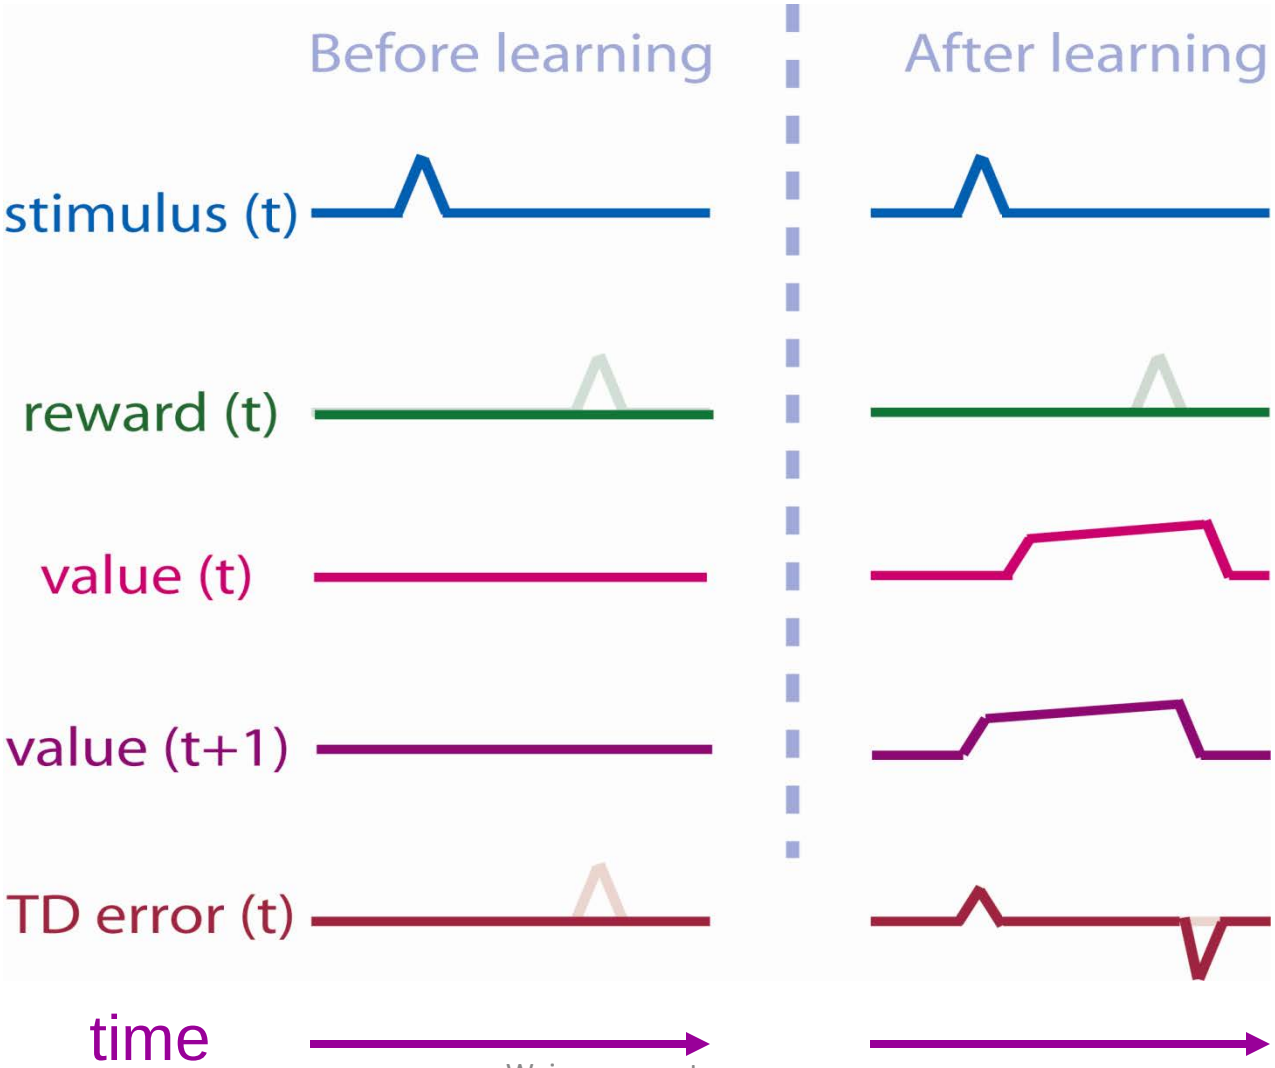
where: $V_{t\,=\,value}$ *of the state reached at time t in iteration k*

r_t *= reward given at time t;* η *= learning rate,* δ *= prediction error*

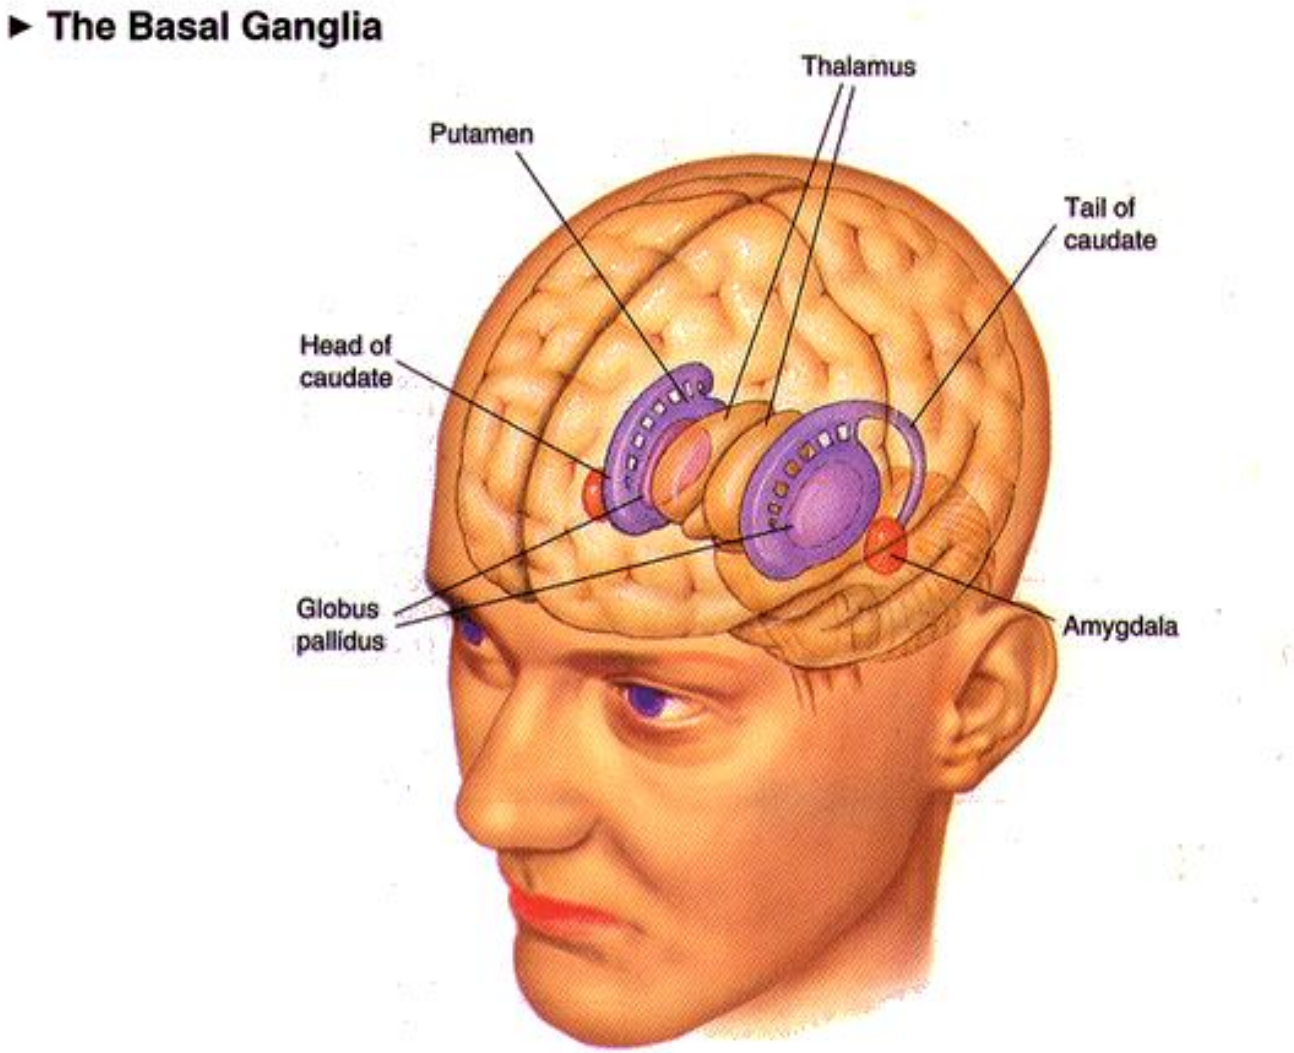
TD error: $\delta_t = r_t + \gamma V_{t+1} - V_t$



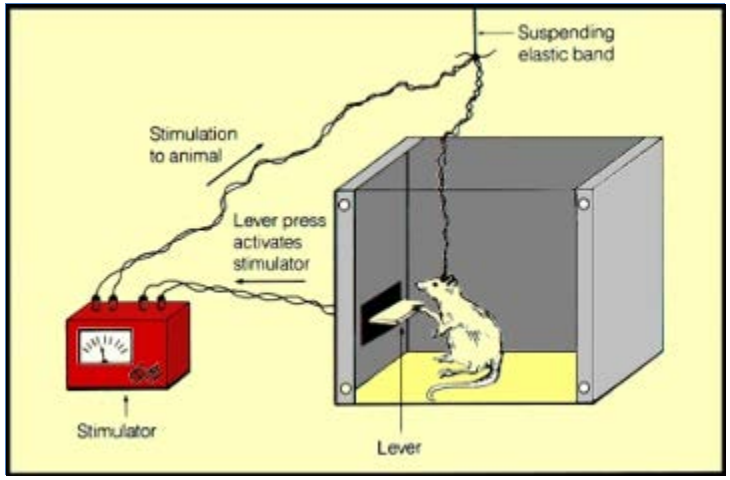
TD error: $\delta_t = \gamma V_{t+1} - V_t + r_t$



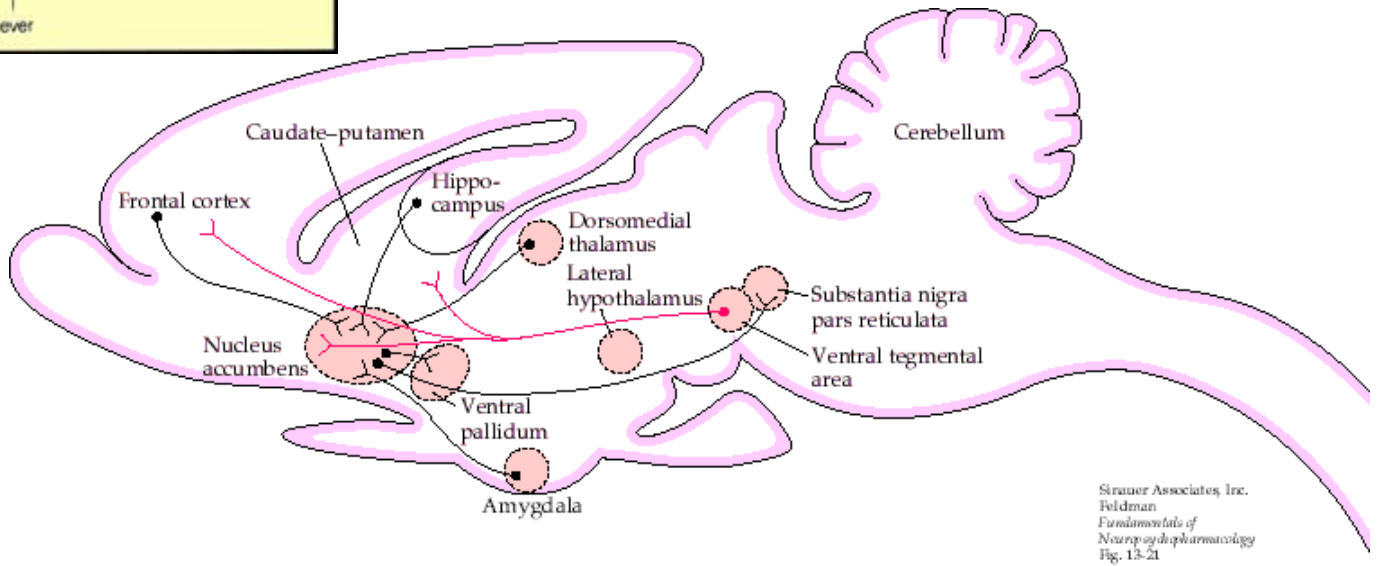
Basal ganglia - anatomy



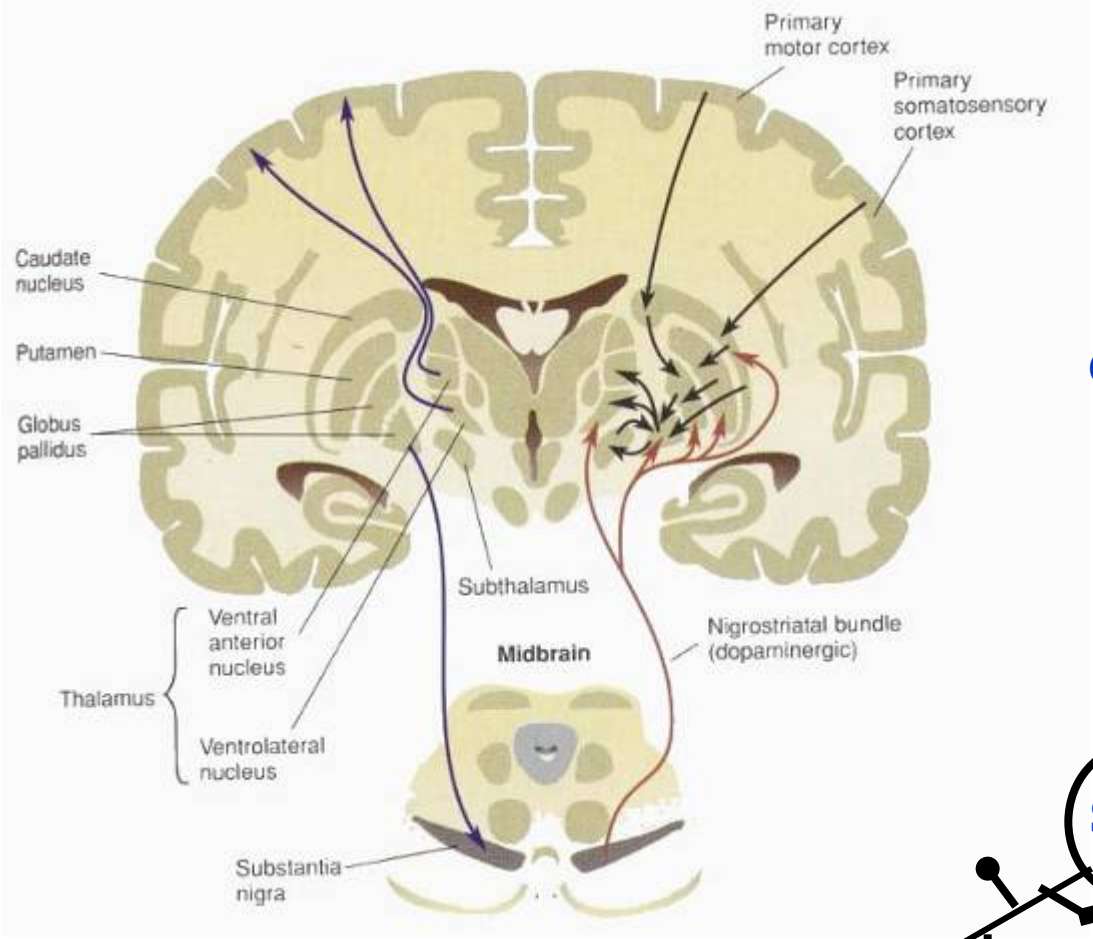
Intracranial self stimulation

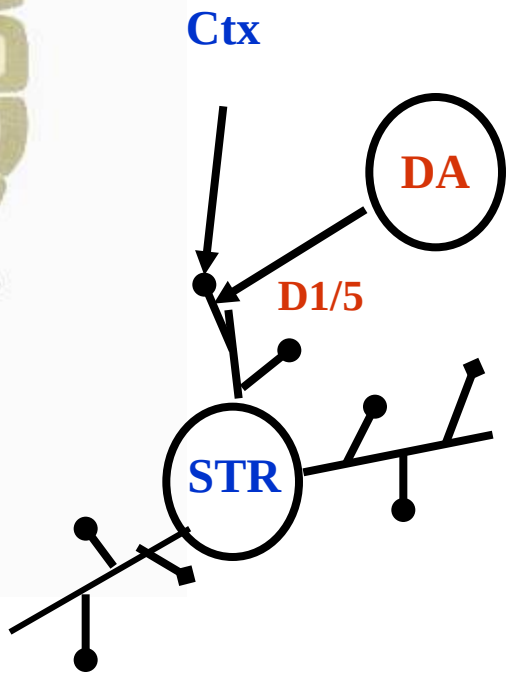


ACTIVATES REWARD CIRCUITS

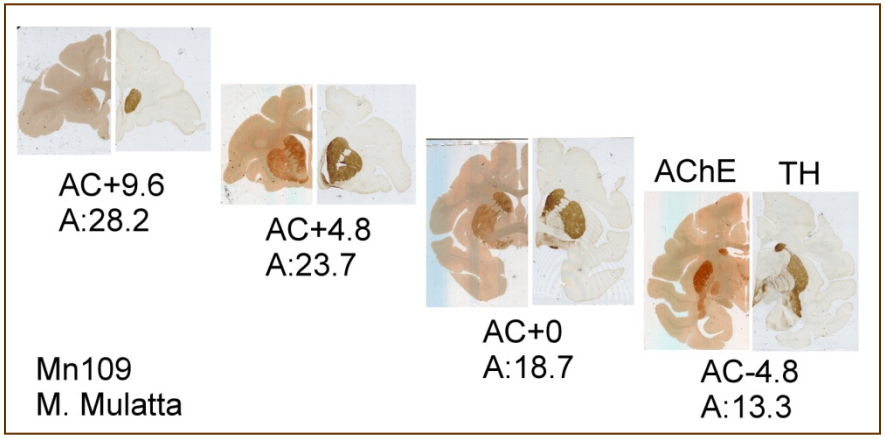


The midbrain dopamine system

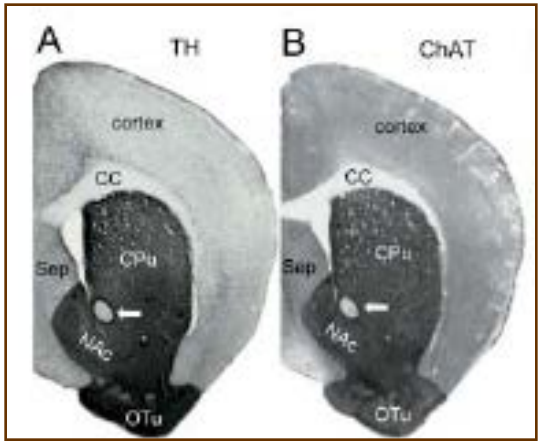




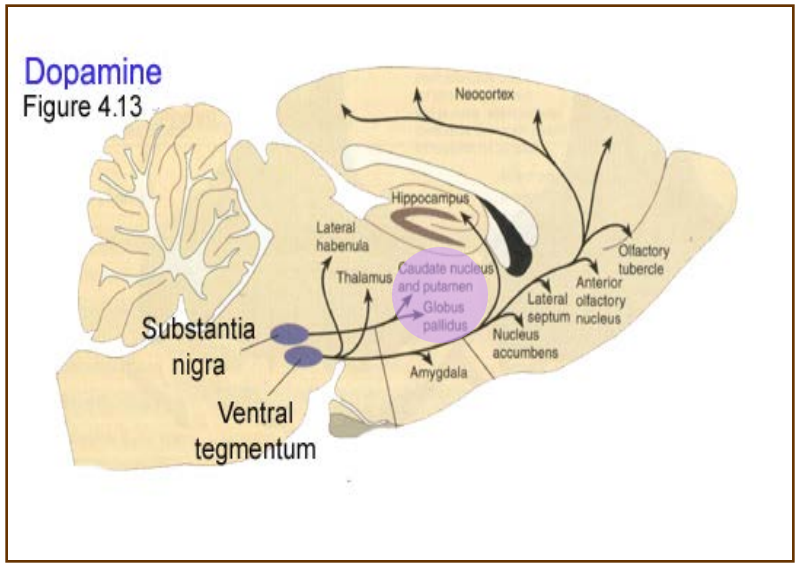
Dopamine and acetylcholine meet in the striatum

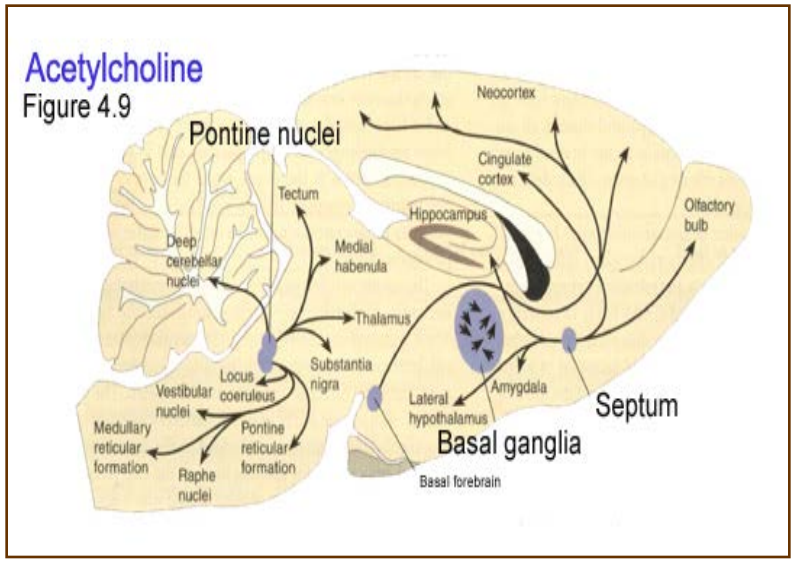


Monkey



Mouse

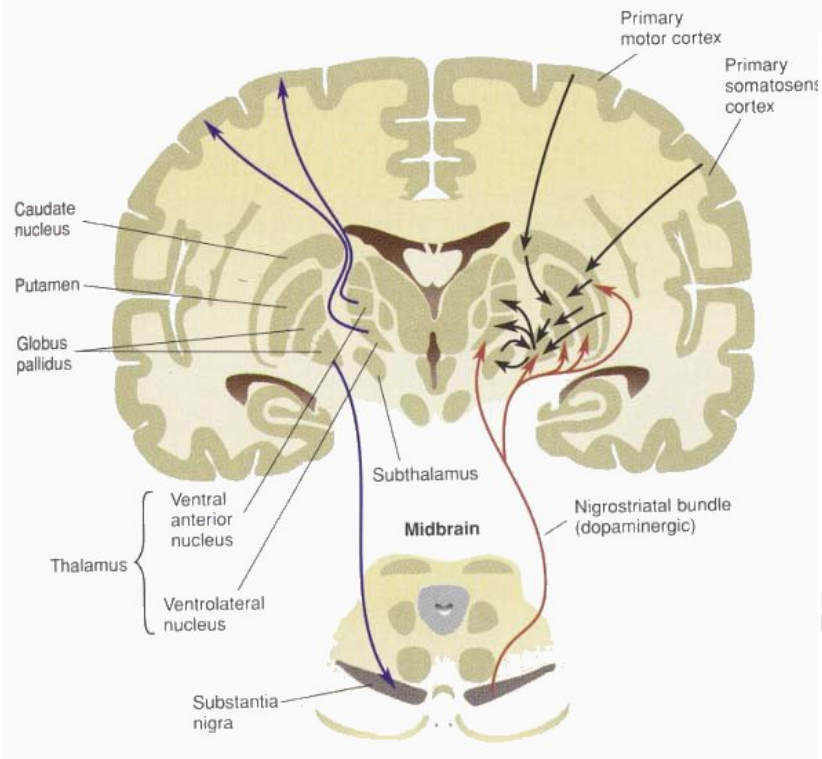


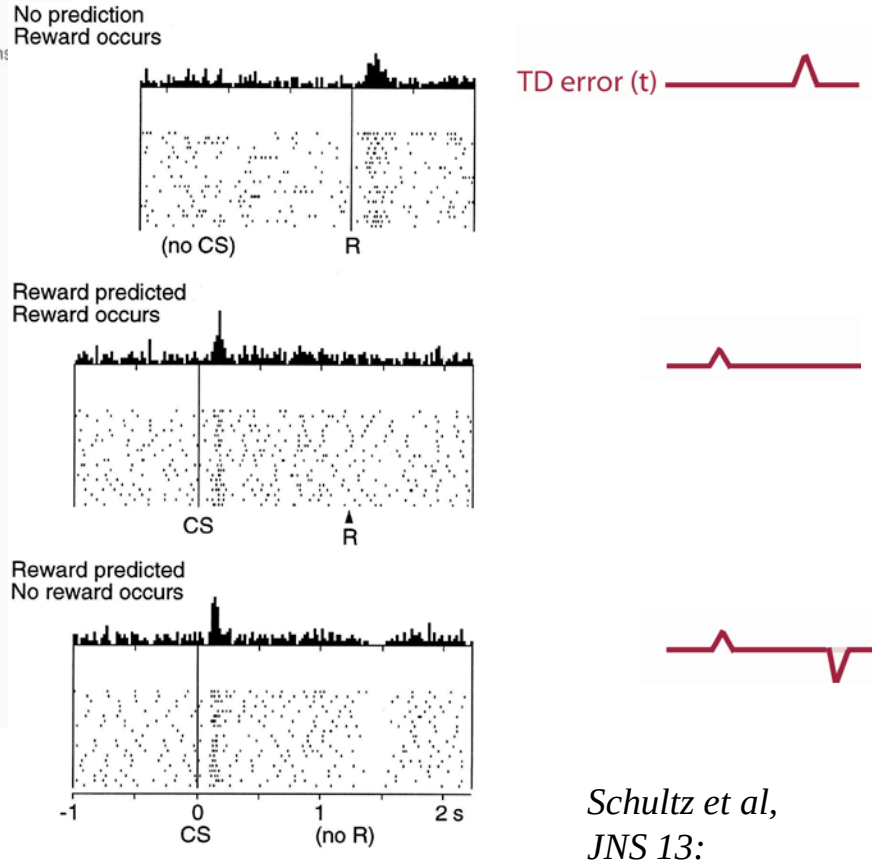


Facts to remember (1)

- Basal ganglia receive cortical input
- Basal ganglia project to frontal cortex
- Dopamine and acetylcholine localization

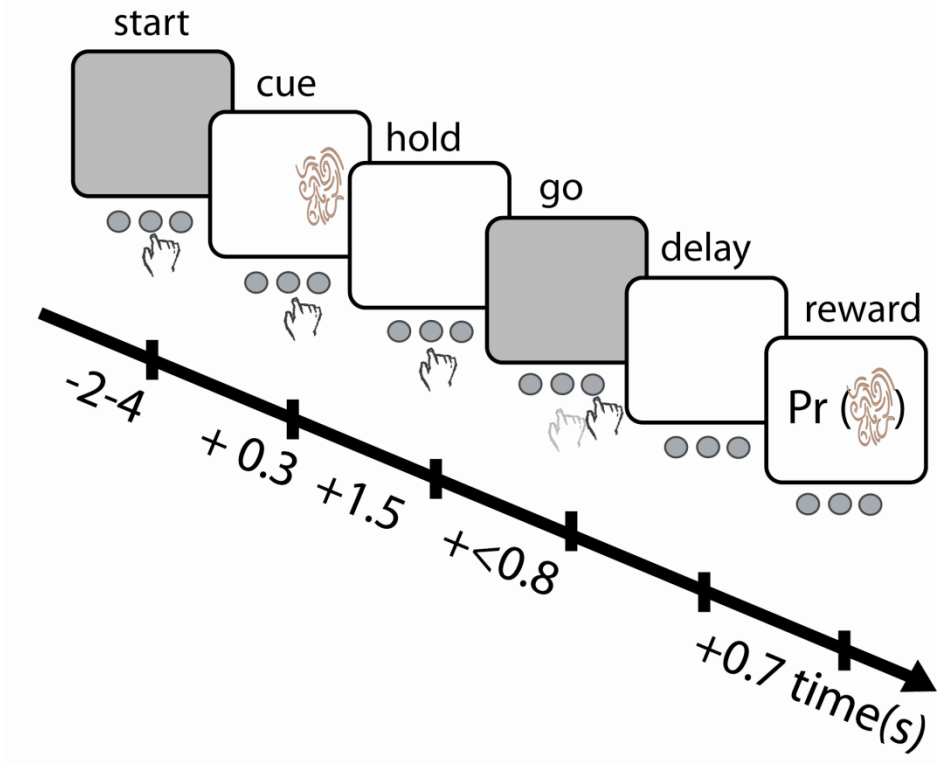
The midbrain dopamine system



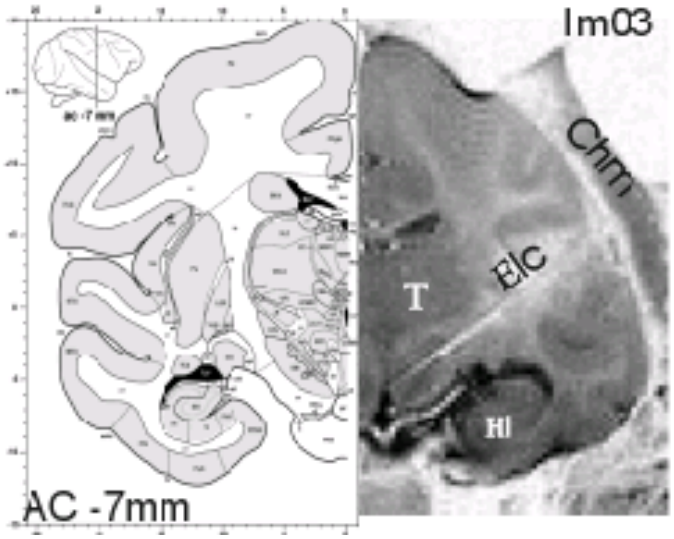


Schultz et al, JNS 13: 900-913 ,1993

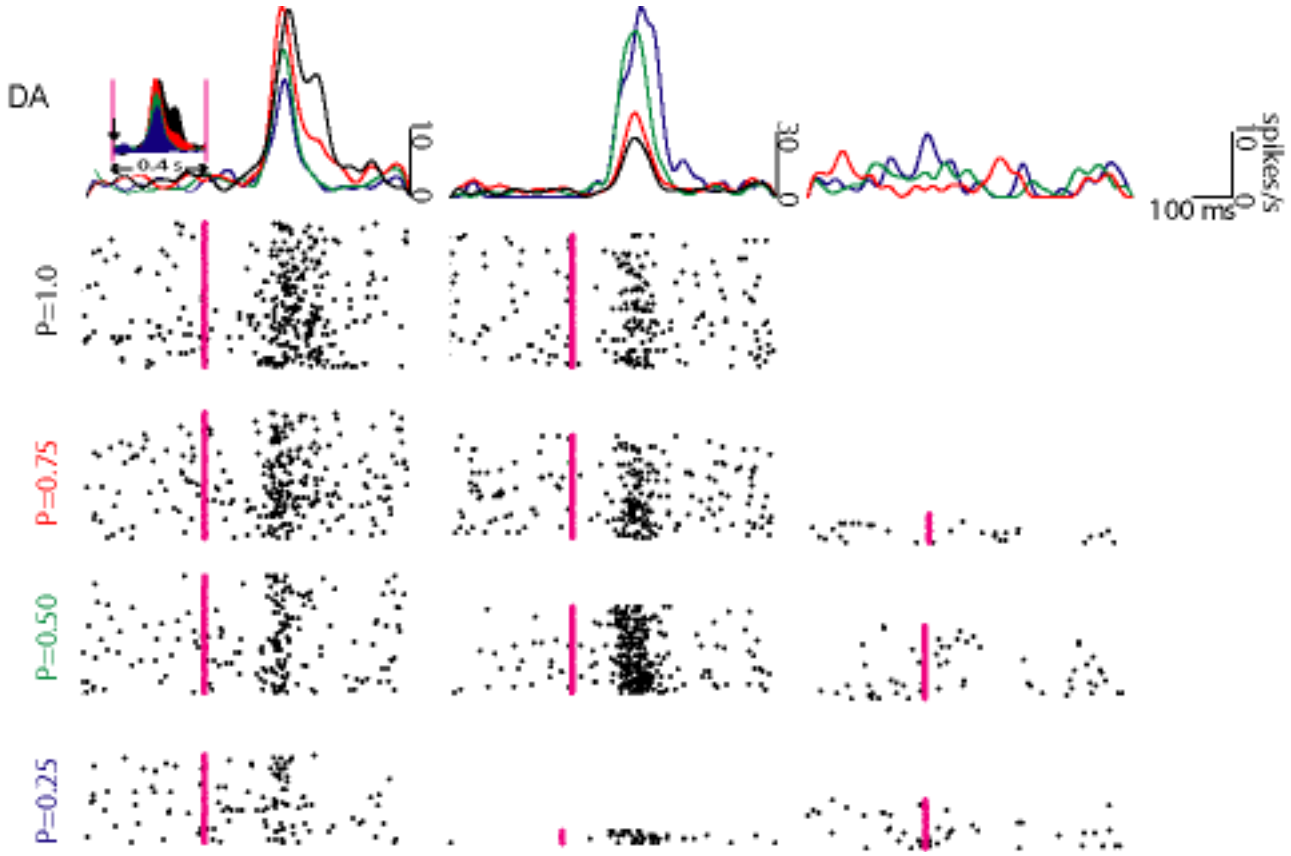
Probabilistic instrumental conditioning task



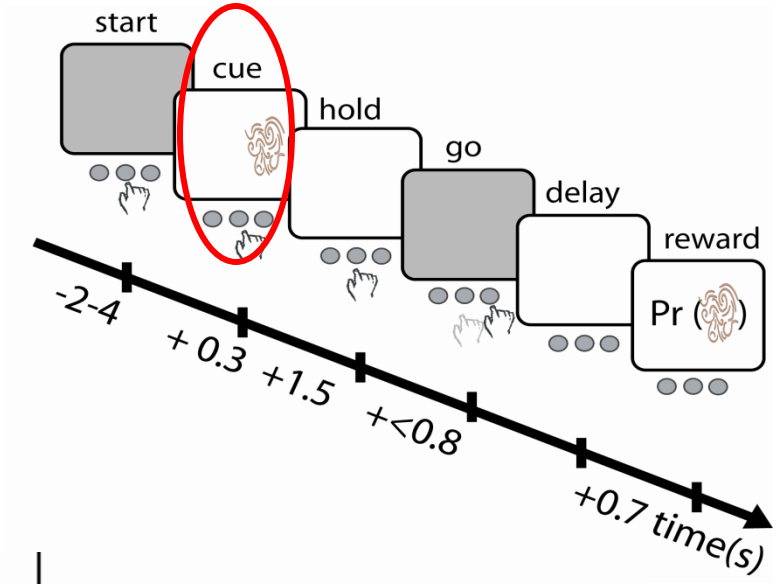
$$\delta_t = \gamma V_{t+1} - V_t + r_t$$

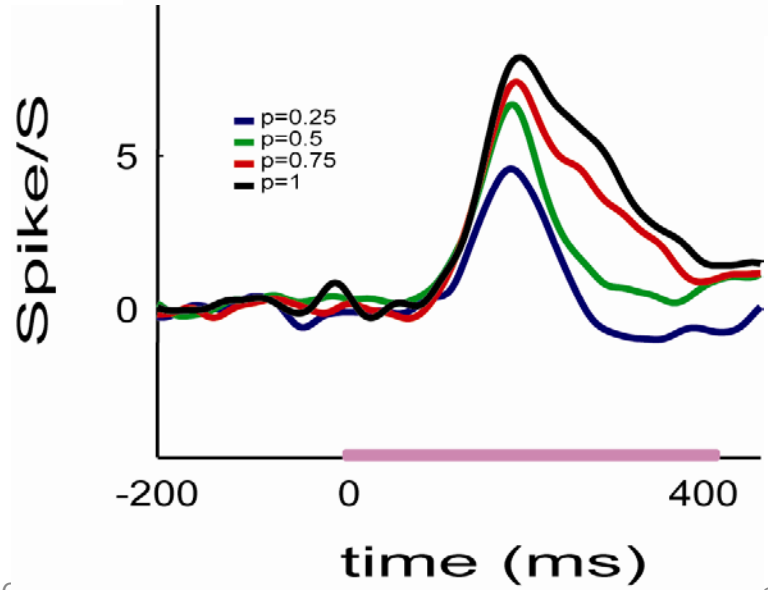


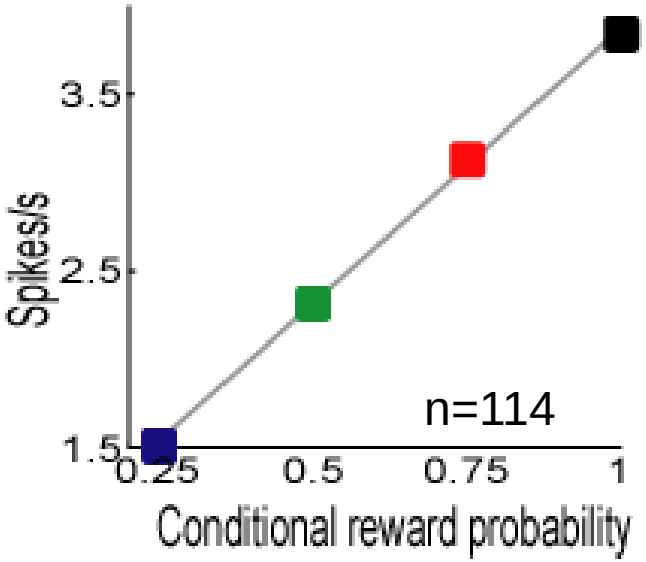
DA response



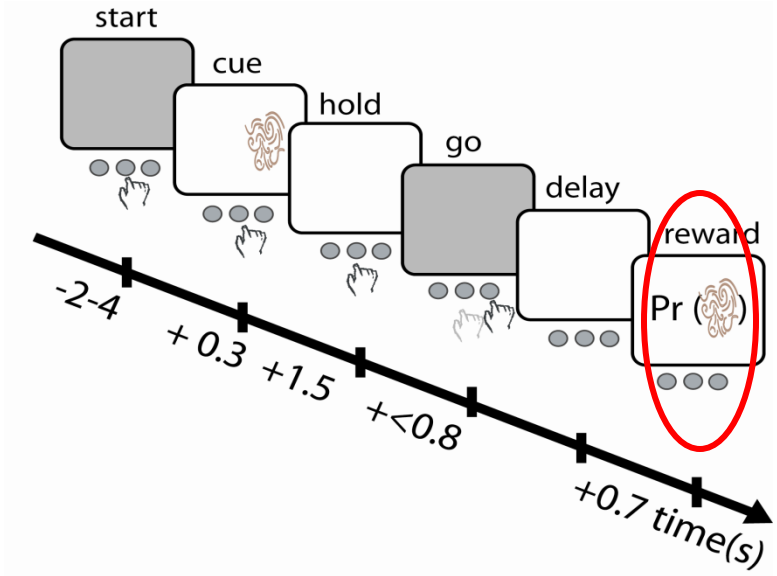
Dopamine population response-cue

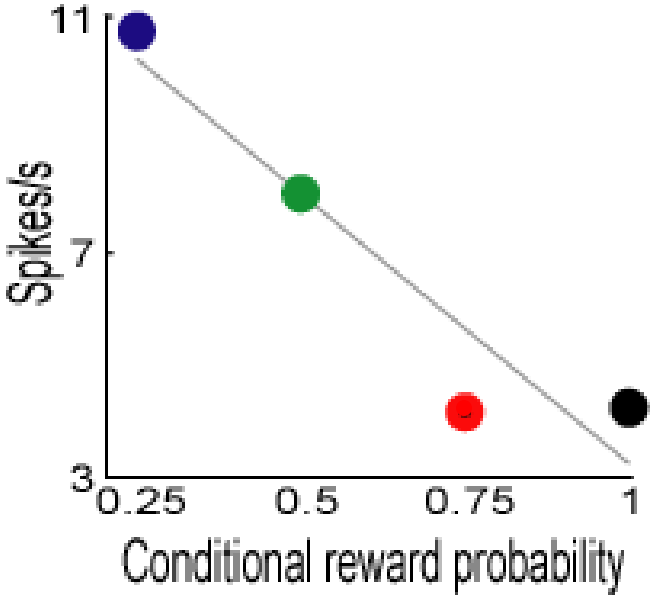


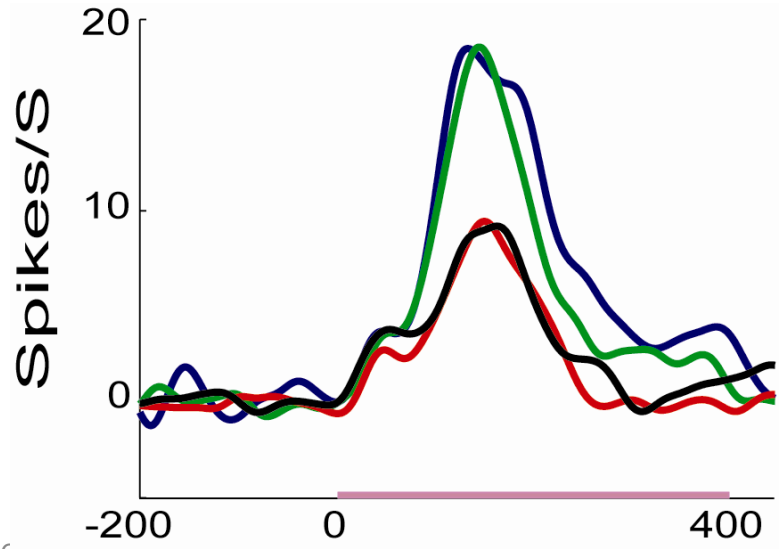




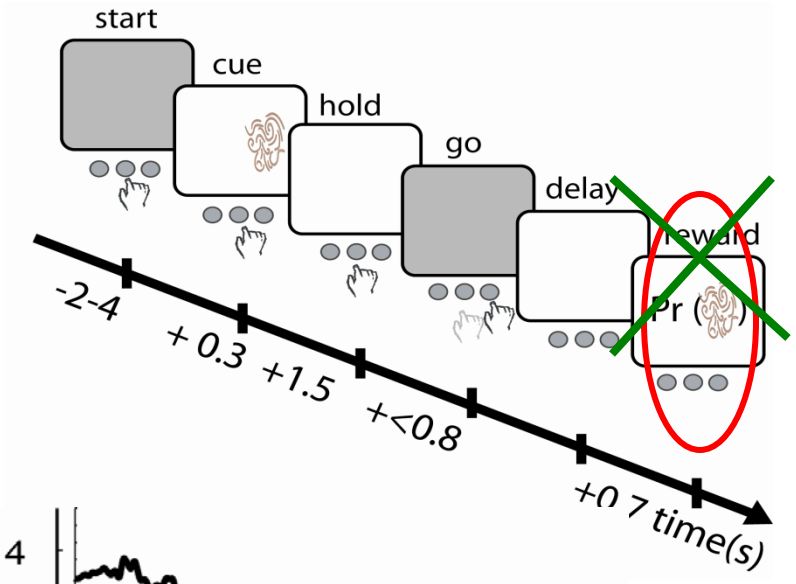
Dopamine population response-reward

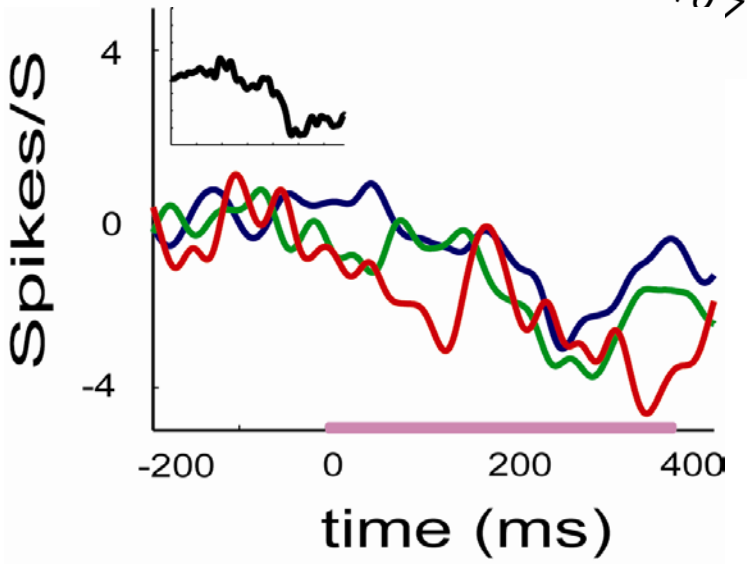


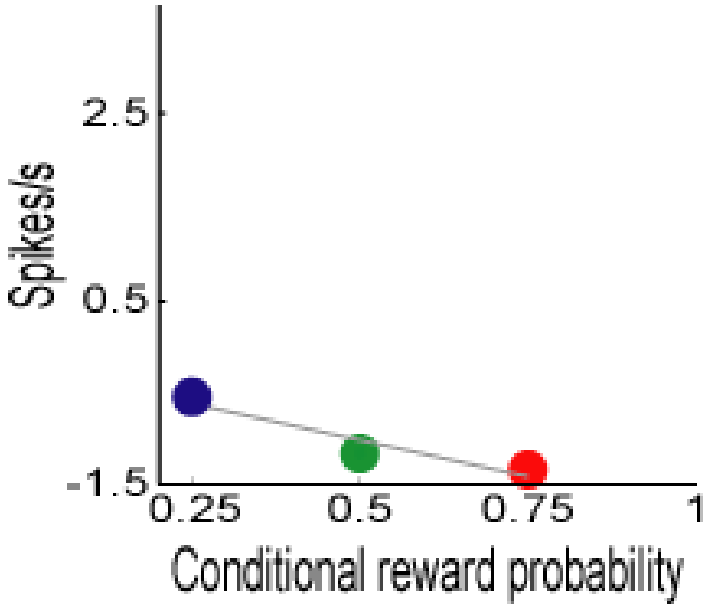




Dopamine population response – reward omission



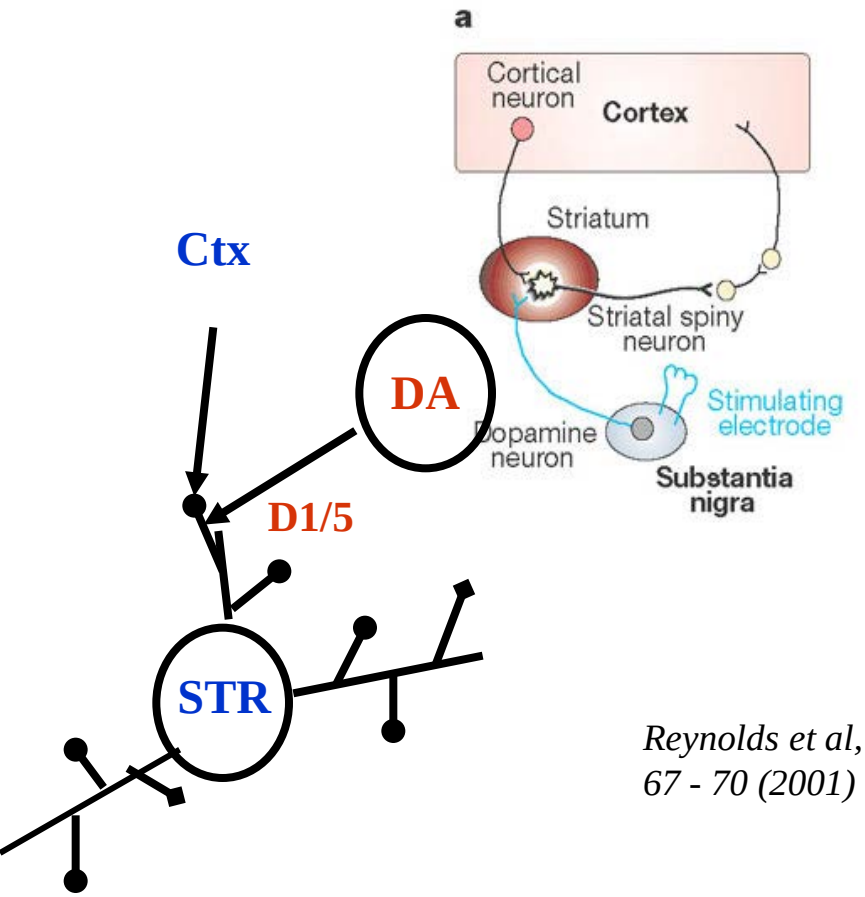


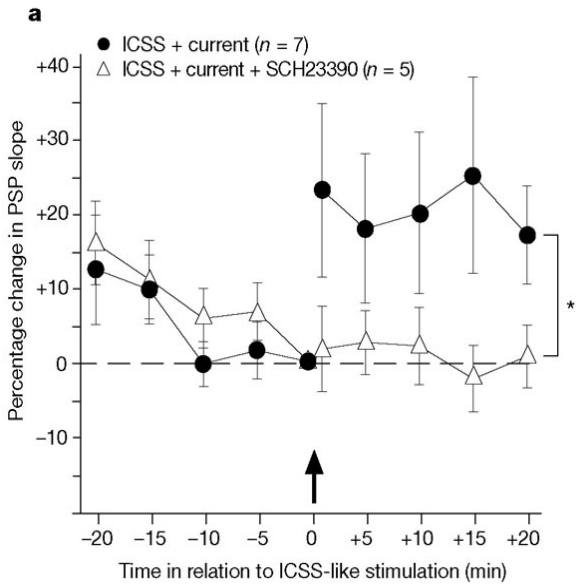


Instrumental conditioning - results

- Responses to visual cue are correlated with future reward probability
- Responses to reward are inversely correlated with reward probability
- Responses to reward omission are indifferent to reward probability
- Dopamine neurons provide an accurate TD signal (but only in the positive domain)

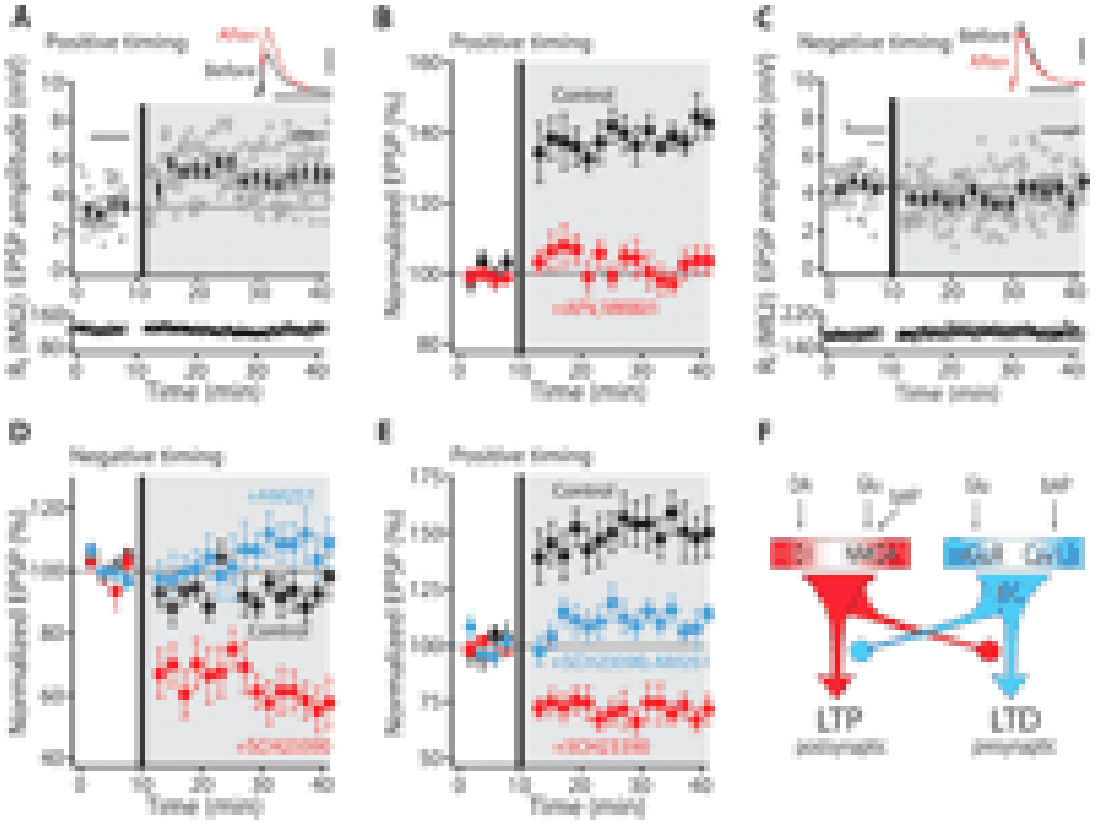
… and it can cause long term plasticity of cortico-striatal synapses





Reynolds et al, A cellular mechanism of reward-related learning Nature 413, 67 - 70 (2001)

… and it can cause long term plasticity of cortico-striatal synapses

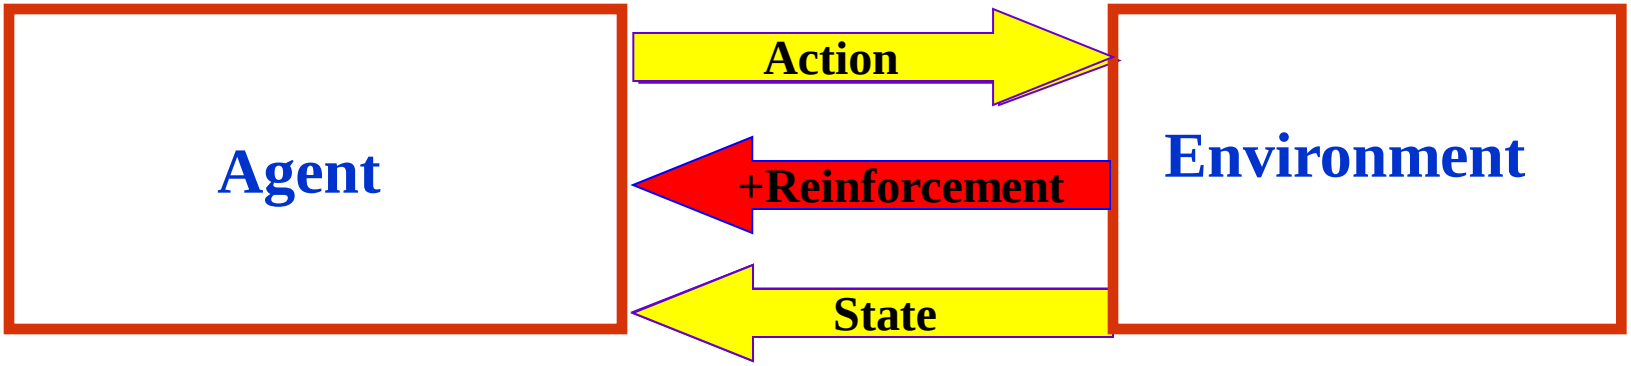


Shen et al., 2008

Facts to remember 2

- DA neurons provide a TD error signal
- To the cortico (state) striatal (action) synapses
- And DA modulates synaptic plasticity

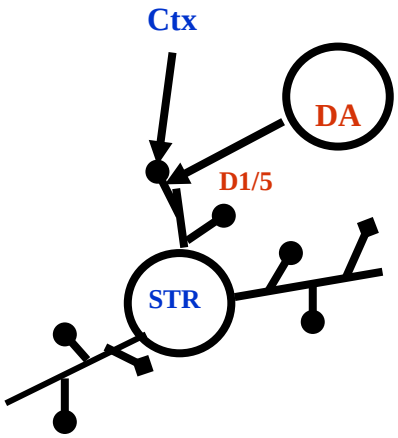
Control - Adding action

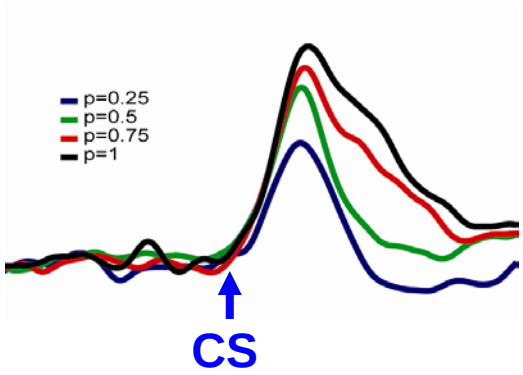


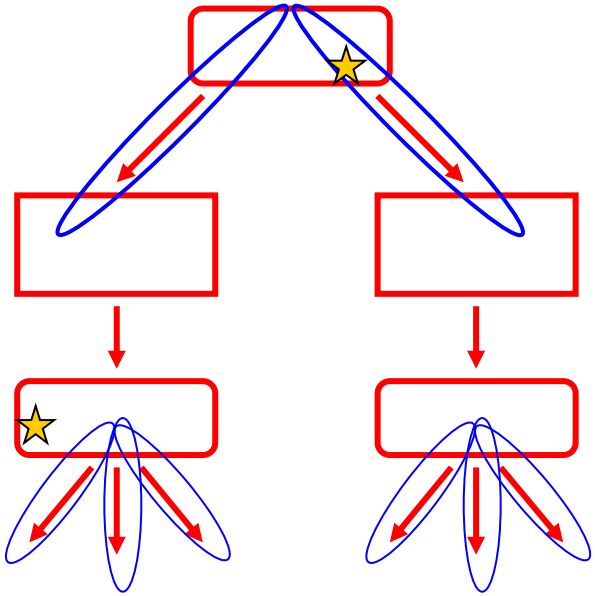
The agent has to:

- Learn to predict reinforcement *state value*
- Know the state-action-state transitions *behavioural policy*

Alternatively – reinforce action

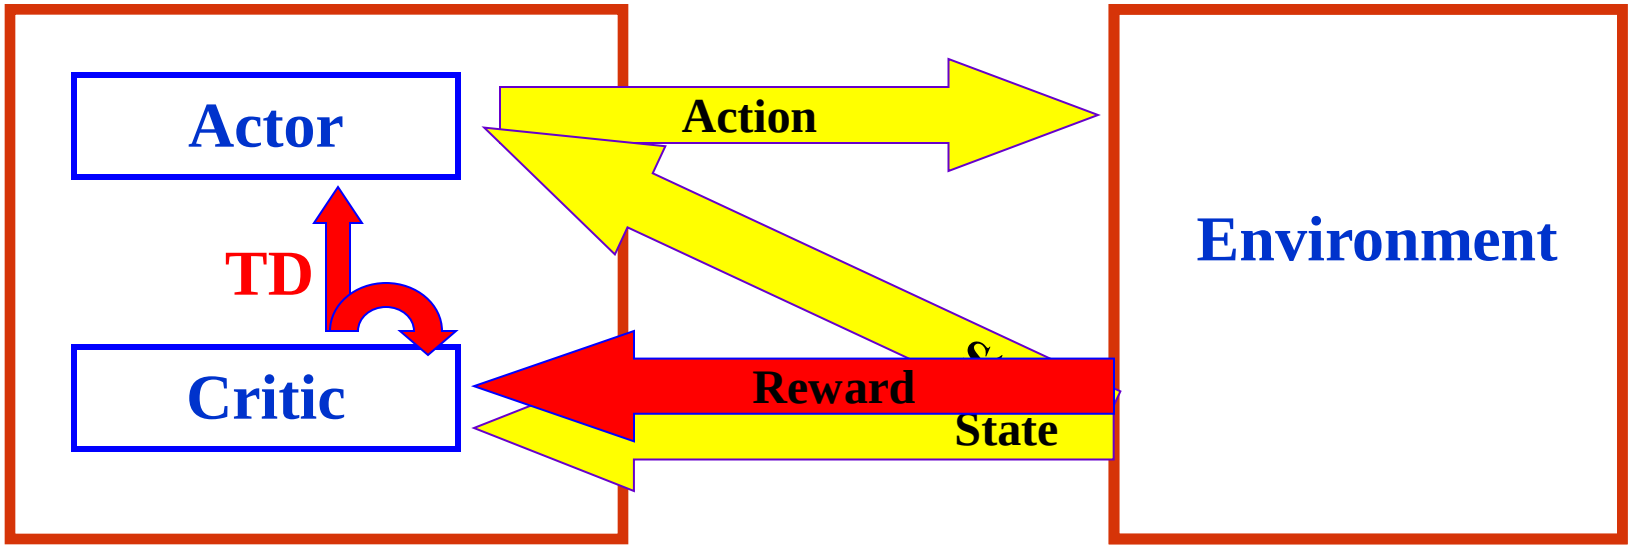






No explicit knowledge about the future

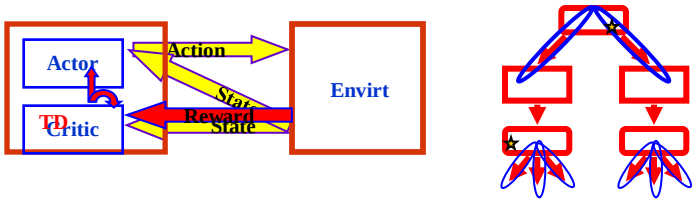
Solution 1: actor/critic networks

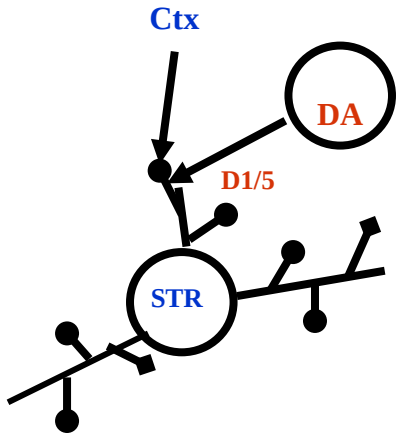


How can the dopamine signal contribute to decision behaviour?

- Long term policy-shaping effect

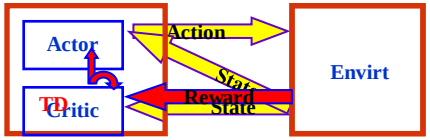
  through synaptic plasticity

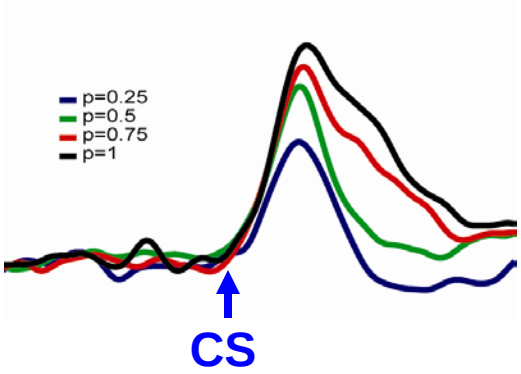




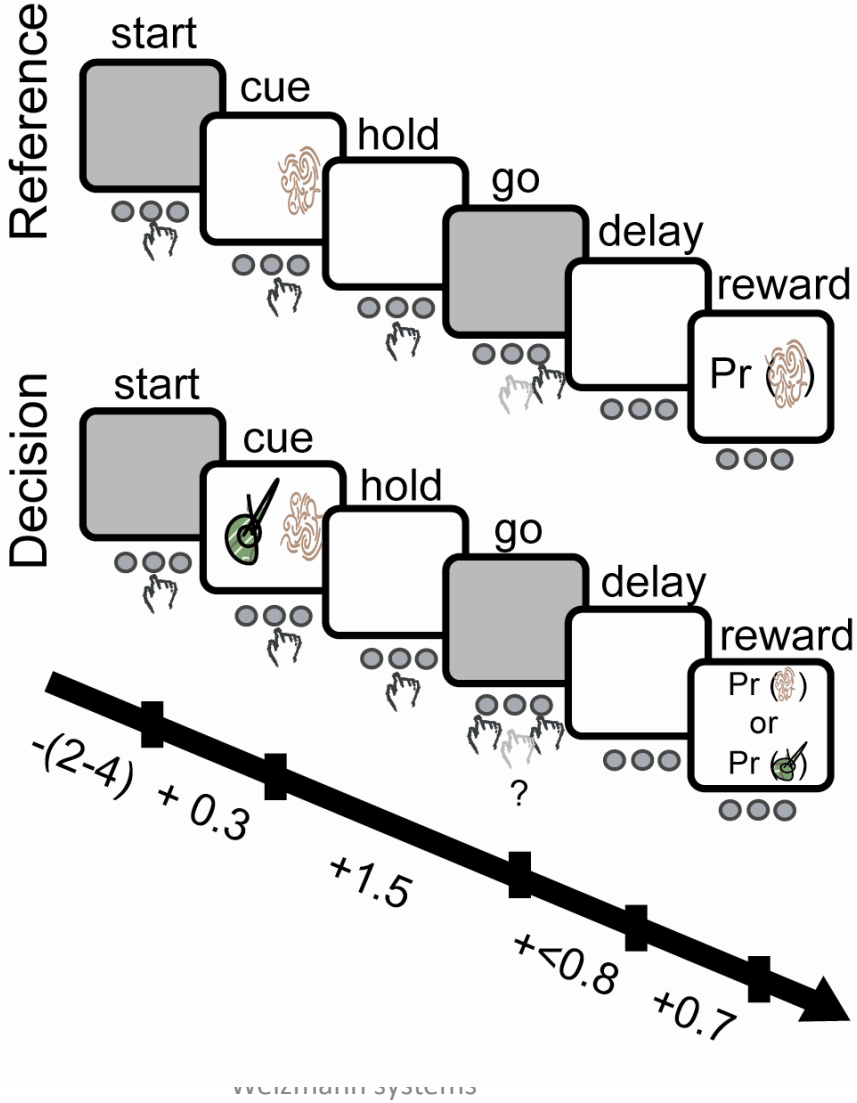
- Immediate effect on action

$$P_{action} = \frac{1}{1+e^{-m\delta(t)+b}}$$

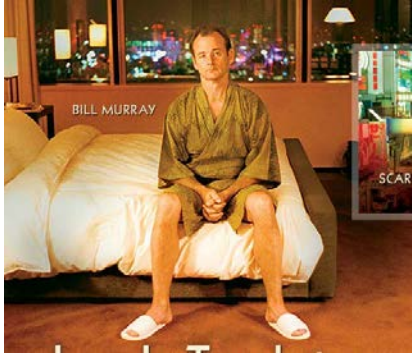


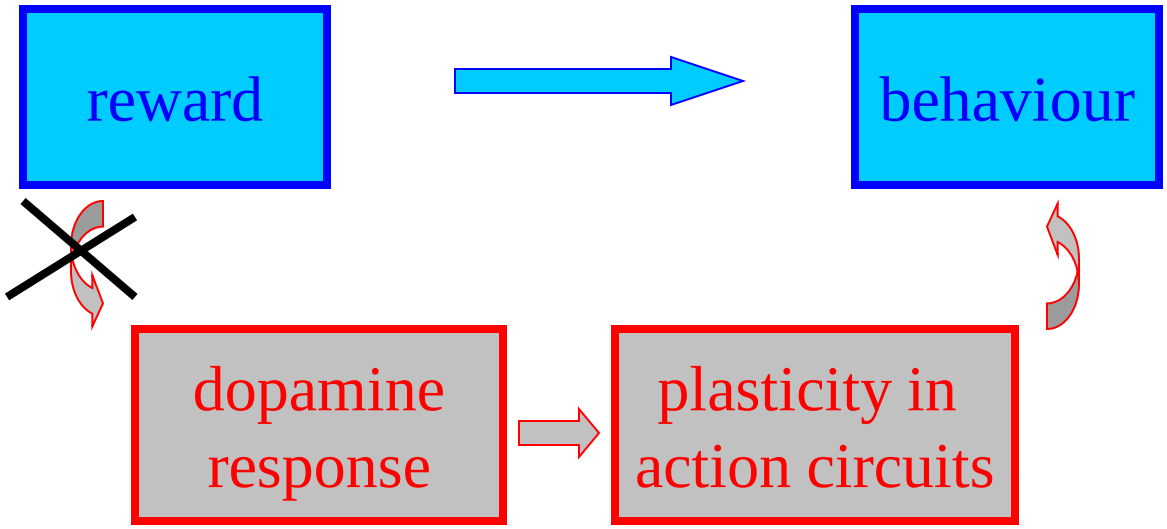


The two armed bandit task

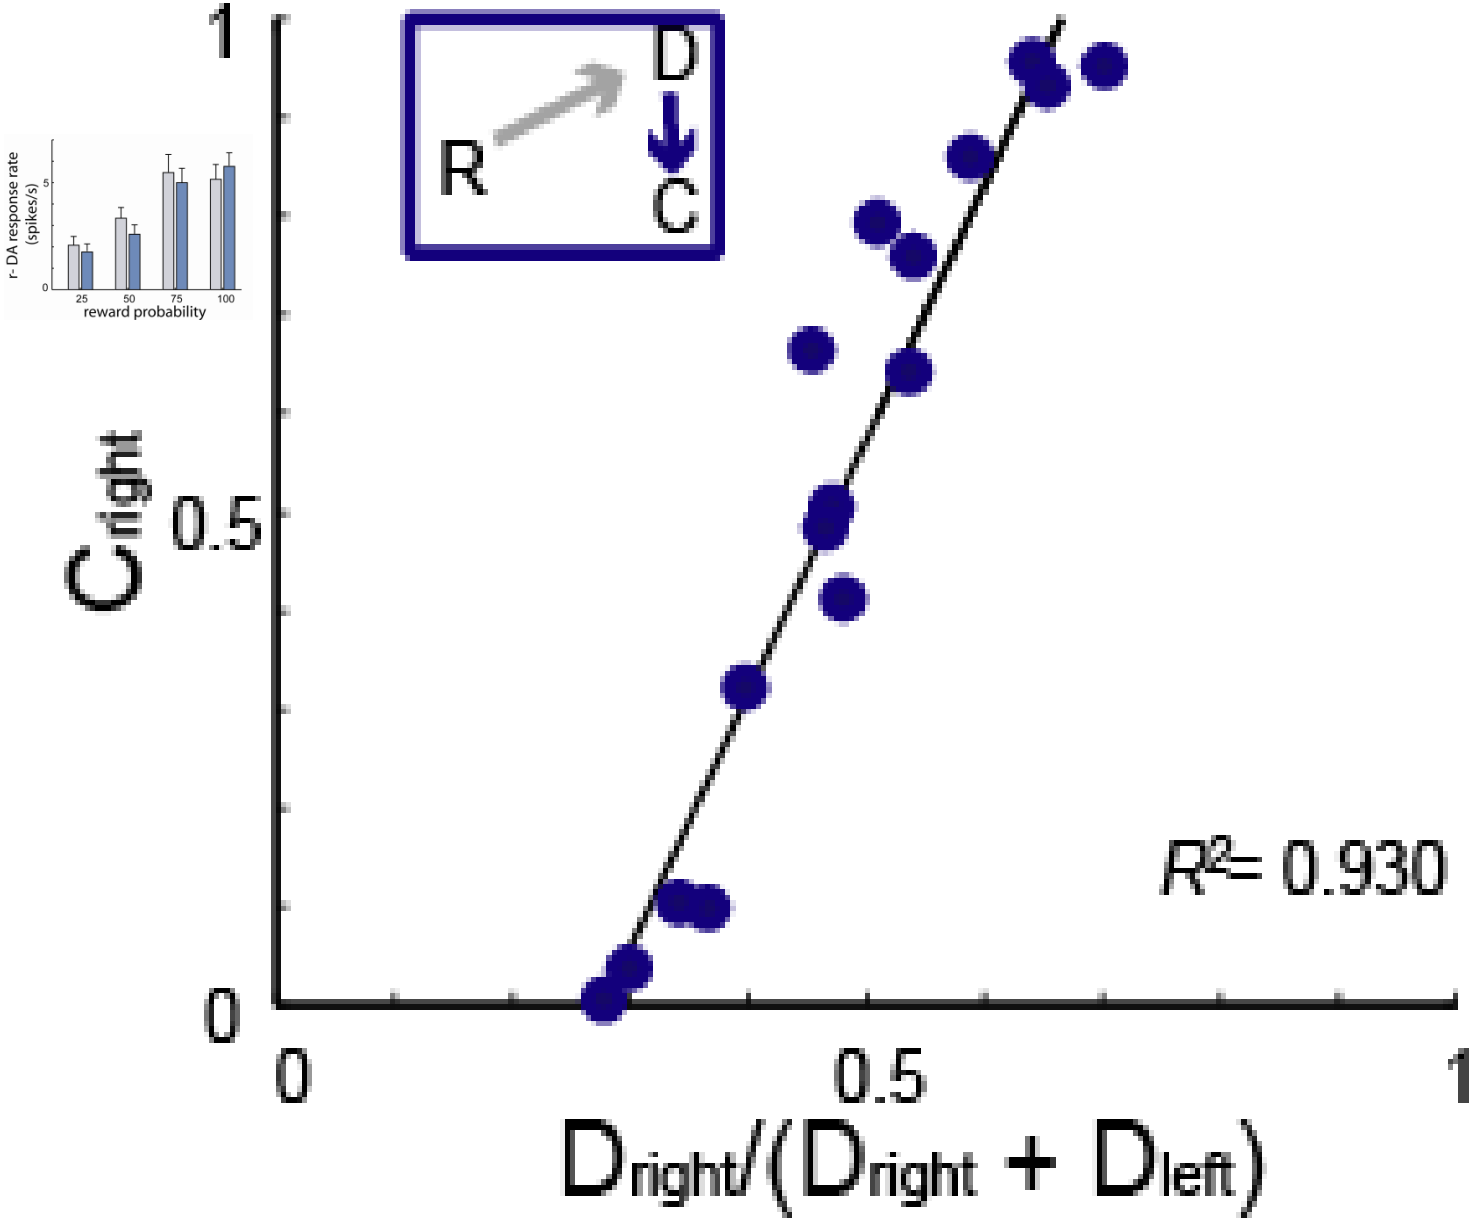


Lost in translation?

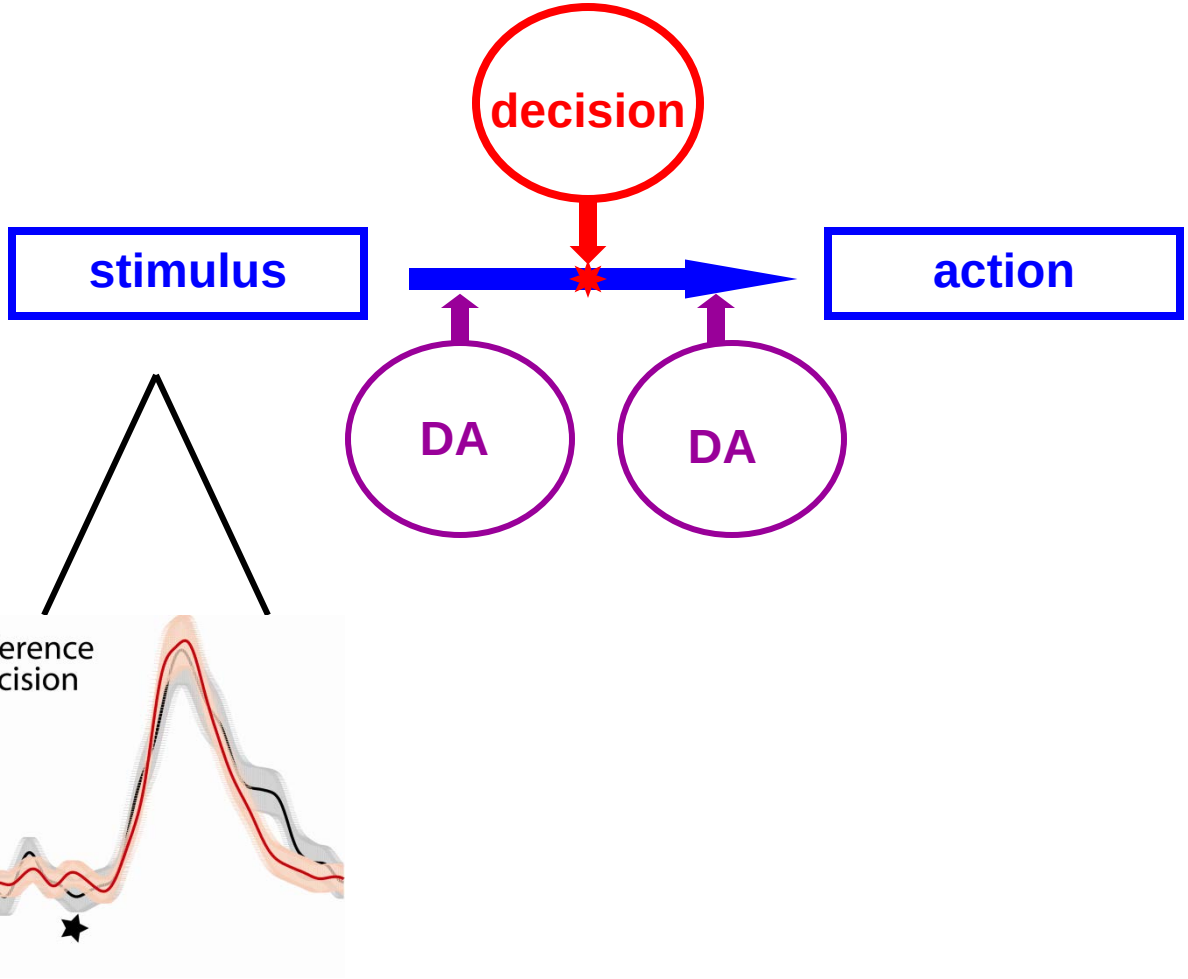




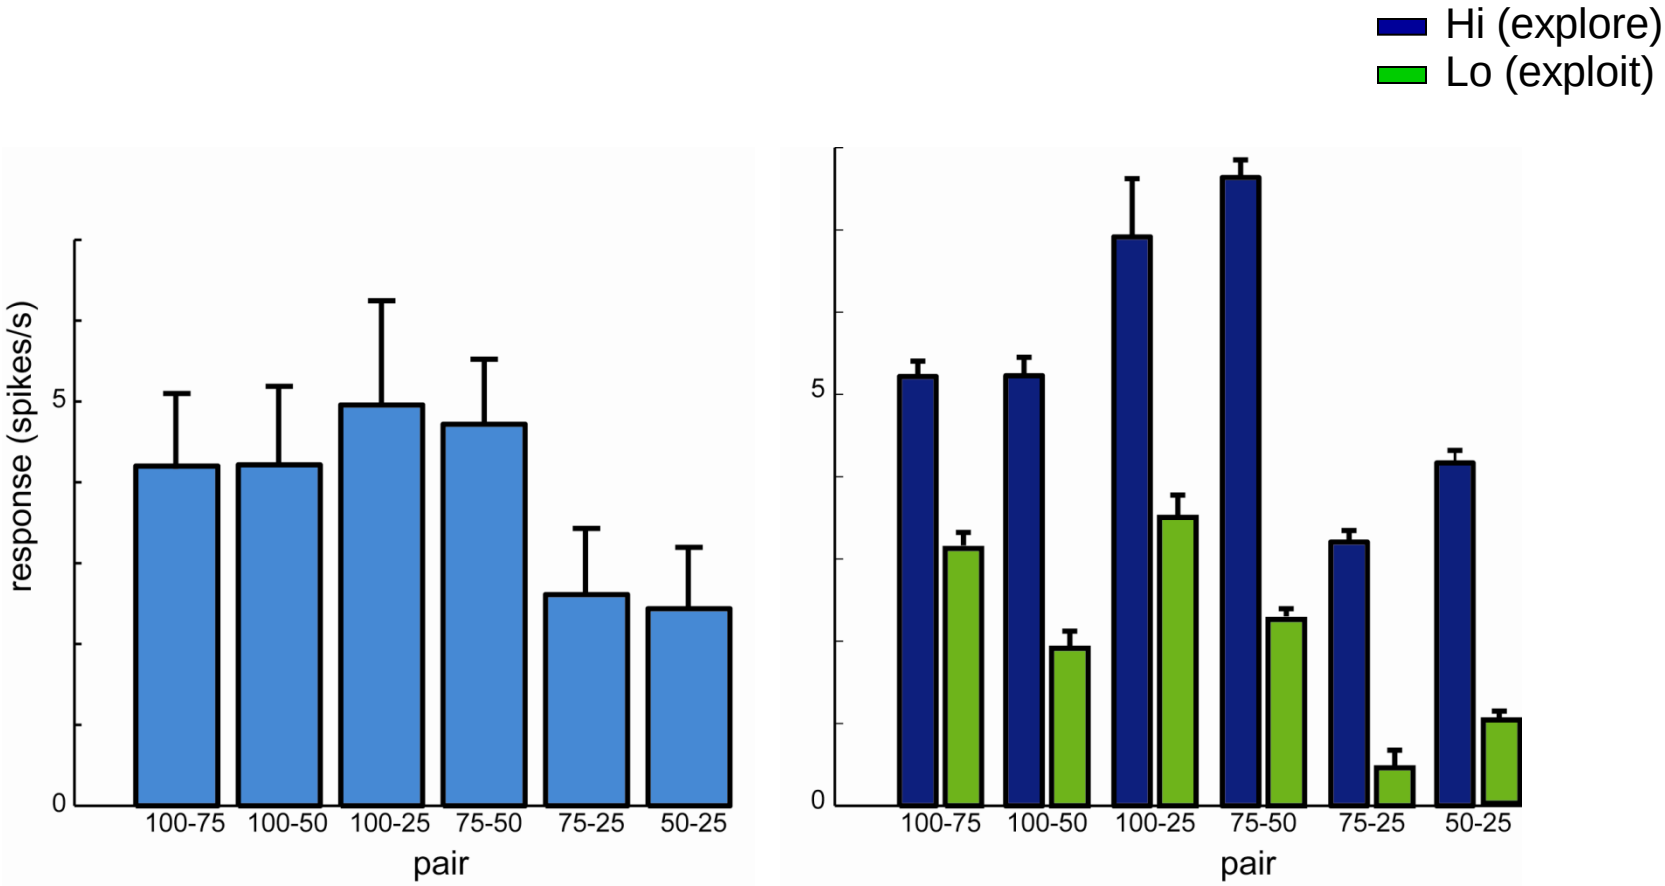
Monkeys' decisions: shaping by dopamine



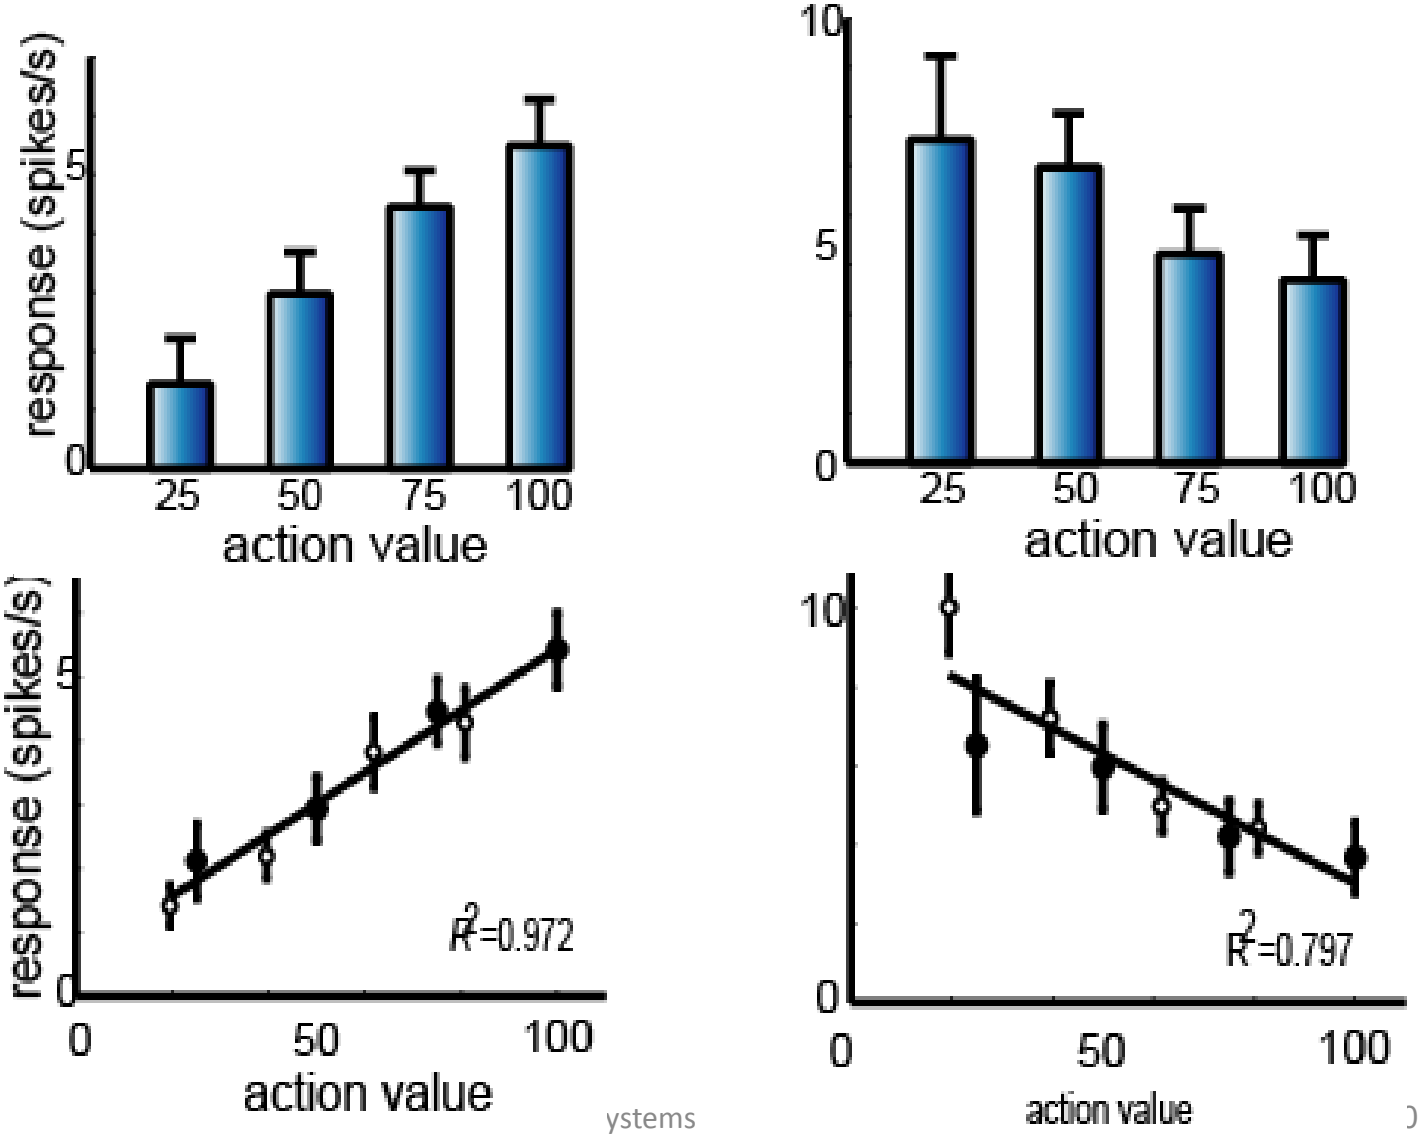
Dopamine neurons during decision



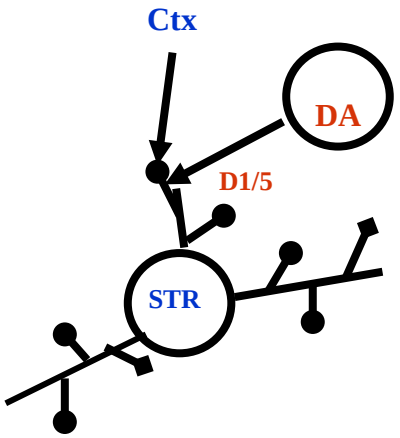
Are DA neurons aware of future choice

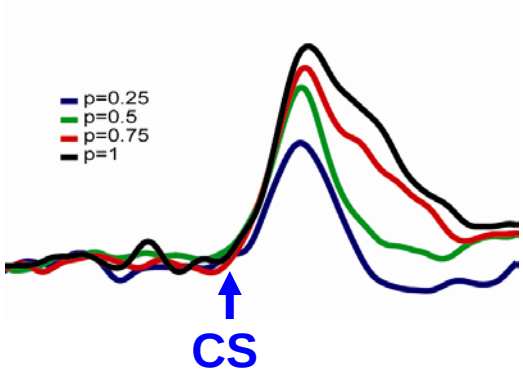


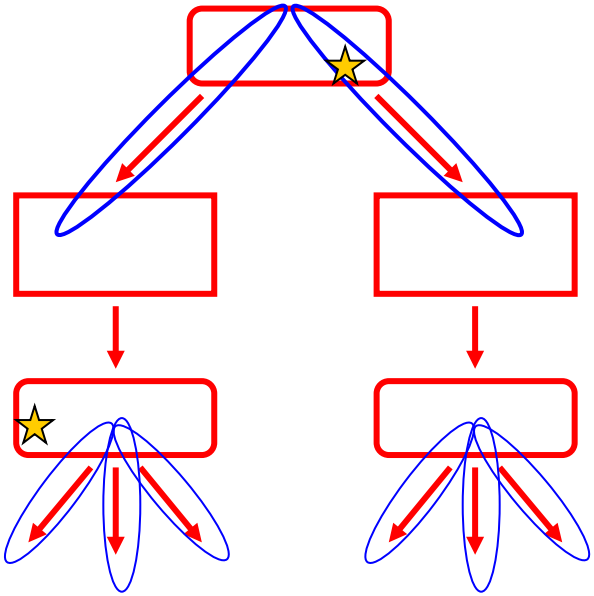
The learning is of state-action values



Adding an internal model

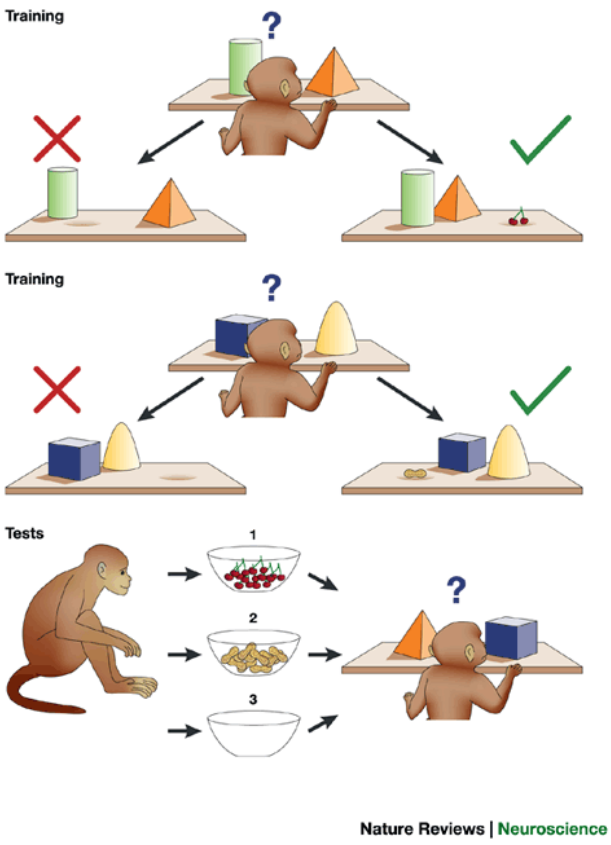






- No explicit knowledge about the future is necessary
- But what about planning?

Reinforcement devaluation – evidence for model



Planning and decision making

Model Free Learning

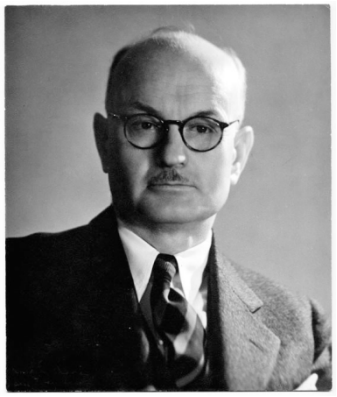
Schultz, 1997

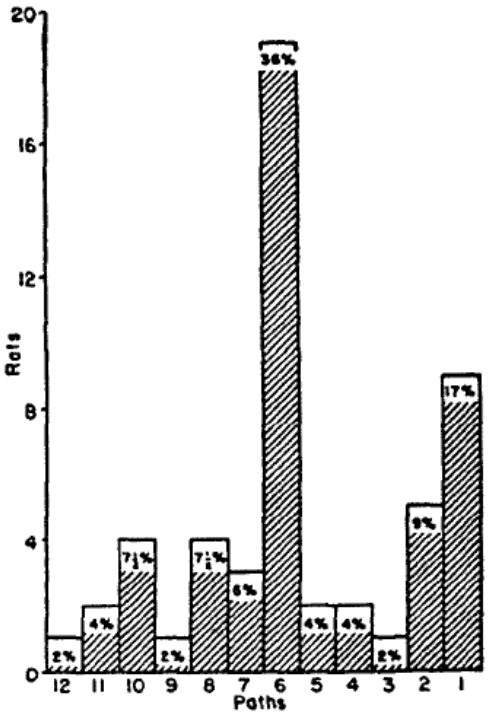
Model based learning

- Creating an internal model of the environment
- Supported by PFC and Nac
- **Where is the model?**
- **How is it learnt?**

A cognitive map of space in the brain?

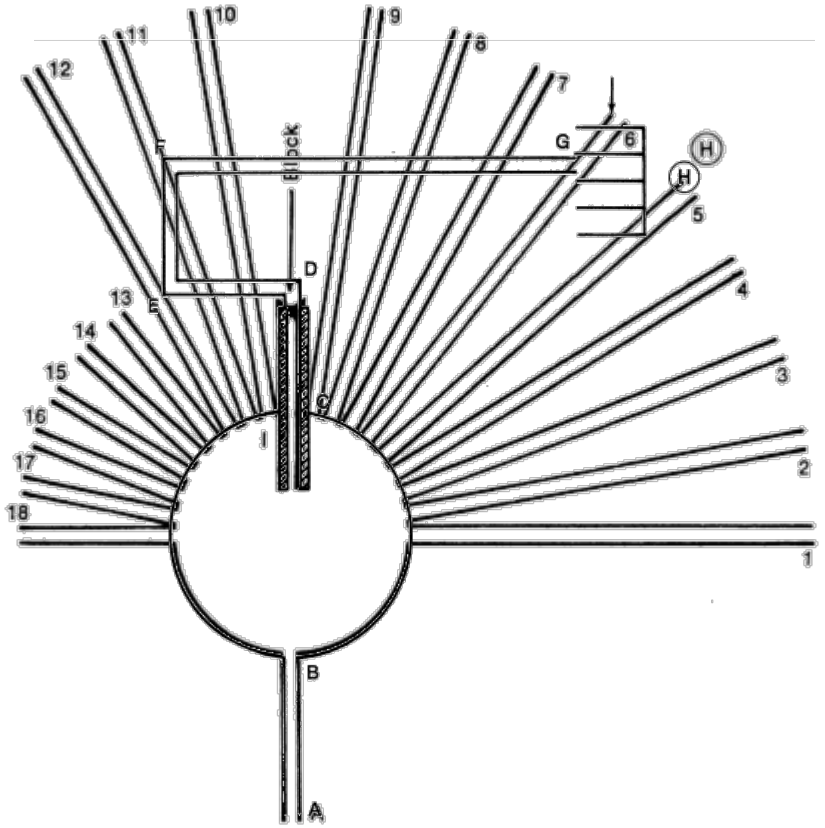


Edward Tolman



Numbers of rats which chose each of the paths

FIG. 17



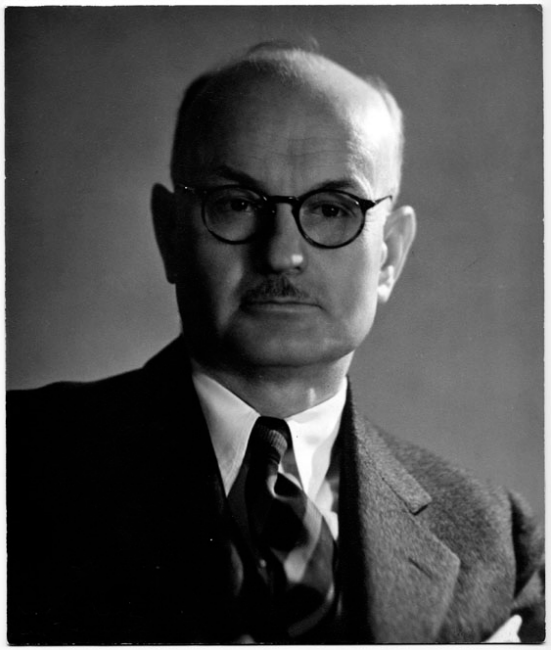
- Not everything is stimulus response
- Rather, there are internal representations
- **Cognitive maps** as an example of an internal/mental representation

Tolman EC (1948) Cognitive maps in rats and men. Psychol Rev 55:189-208.

Model based learning

We believe that in the course of learning something like a field map of the environment gets established in the rat's brain… Although we admit that the rat is bombarded by stimuli, we hold that his nervous system is surprisingly selective as to which of these stimuli it will let in at any given time… Rather, the incoming impulses are usually worked over and elaborated in the central control room into a tentative, cognitive-like map of the environment. And it is this tentative map, indicating routes and paths and environmental relationships, which finally determines what responses, if any, the animal will finally release.

Cognitive maps of rats and men (1948)
The Psychological Review, 55(4), 189-208



Edward C. Tolman
