Physical Implementation of a quantum computer

David Divincenzo's criteria:

1. Well defined qubits.
2. Initialization to a pure state
3. Universal set of quantum gates.
4. Qubit specific measurement.
5. Long coherence times (compared with gate & meas. time).

Universal Gate set

- For N qubits, a general unitary transformation U acts on a 2^N - dimension Hilbert space.
- A *finite* set of unitary gates that spans any such U .
- The Deutsch-Toffoli gate

- D. Deutsch, *Proc. R. Soc. London, Ser. A*, **425**, 73, (1989).

Universal Gate set

- For N -qubits, and unitary transformation U on a 2^N -dimension Hilbert space.
- A *finite* set of unitary gates that spans any such U .

Single qubit gate

$$U \in SU[2]$$

2-qubit C-not gate

- Rotations can be approximated to ε by concatenating k gates, from a finite set $\{V_i\}$, where $k < \text{polylog}(1/\varepsilon)$.

- Barenco et. al. *Phys. Rev. A*, **52**, 3457, (1995).

Physical Implementation of a quantum computer

David Divincenzo's criteria:

How well???

Well enough to allow for a large scale computation:
Fault tolerance

$$F = \langle \Psi | \rho_\epsilon | \Psi \rangle \quad \epsilon = 1 - F$$

Fault-tolerant Quantum Computation

Noisy operations ϵ

One level quantum error-correction codes $O((\epsilon/\epsilon_0)^2)$

concatenation;
threshold theorem

k-levels of fault-tolerant encoding
 $O((\epsilon/\epsilon_0)^{2^k}) \rightarrow 0$ if $\epsilon < \epsilon_0$

- ϵ_0 Fault tolerance **threshold**.
- Heavy resource requirements when $\epsilon \simeq \epsilon_0$
- Depends on code, noise model, arch. constraints etc.
- Current **estimates** for $\epsilon_0 \simeq 10^{-2} - 10^{-4}$

Tutorial overview

1. The ion-qubit: different ion-qubit choices, Ion traps.
2. Qubit initialization.
3. Qubit measurement.
4. Universal set of quantum gates:
single qubit rotations; two-ion entanglement gates
5. Memory coherence times

How well???

Benchmarked to current threshold estimates

Disclaimer: non exhaustive; focuses on laser-driven gates

- One electron in the valence shell; “Alkali like” $^2S_{1/2}$ ground state.

Electronic levels Structure

$^2S_{1/2}$ Zeeman qubit

(Isotopes w/o nuclear spin)

e.g.

$^{24}\text{Mg}^+$

$^{64}\text{Zn}^+$

$^{114}\text{Cd}^+$

$^{40}\text{Ca}^+$

$^{88}\text{Sr}^+$

$^{138}\text{Ba}^+$

$^{174}\text{Yb}^+$

$^{202}\text{Hg}^+$

Advantages

- RF separation.
- Tunable.
- Infinite T_1 .

Disadvantages

- Energy depends linearly on B.
- Transition photon carries no momentum
- Momentum transfer with off-resonance lasers: photon scattering.
- Detection.

$^2S_{1/2}$ Hyperfine qubit

e.g.

$^9\text{Be}^+$

$^{25}\text{Mg}^+$

$^{67}\text{Zn}^+$

$^{111}\text{Cd}^+$

$^{43}\text{Ca}^+$

$^{87}\text{Sr}^+$

$^{137}\text{Ba}^+$

$^{171}\text{Yb}^+$

$^{199}\text{Hg}^+$

Hyperfine structure (order depends on the sign of A_{hf})

Turn on small B field

Advantages

- MW energy separation.
- B-field independent qubit.
- Infinite T_1 .
- State selective fluorescence Detection.

Disadvantages

- Few GHz energy separation.
- Transition photon carries no momentum
- Off resonance photon scattering.
- initialization to clock transition can be more tricky

$F = I - 1/2$

$m = 0$

$|\uparrow\rangle$

1 - 40 GHz

$m = 0$

$|\downarrow\rangle$

$^2S_{1/2}$

$F = I + 1/2$

Optical qubit

Trapping

- Trap ions: a minimum/maximum to ϕ , the electric potential.
- Impossible in all directions; Laplace's equation:

$$\nabla^2 \Phi = 0$$

Trapping

Linear RF Paul trap

Dynamic trapping (pondermotive forces)

Oscillating electric field:

$$E(x, t) = E_0(x) \cos(\omega_{rf} t + \phi)$$

$$x(t) = X(t) + \xi(t)$$

Large and slow

$$X(t) \gg \xi(t)$$

small and fast

$$\frac{\partial^2 X(t)}{\partial t^2} \ll \frac{\partial^2 \xi(t)}{\partial t^2}$$

Newton's E.O.M:

$$m \left(\frac{\partial^2 X(t)}{\partial t^2} + \frac{\partial^2 \xi(t)}{\partial t^2} \right) = e E_0(x) \cos(\omega_{rf} t + \phi)$$

Dynamic trapping

$$m\left(\frac{\partial^2 X(t)}{\partial t^2} + \frac{\partial^2 \xi(t)}{\partial t^2}\right) = eE_0(x) \cos(\omega_{rf}t + \phi)$$

Field expansion:

$$E_0(x) = E_0(X) + \frac{\partial E_0(X)}{\partial X} \xi + O(\xi^2)$$

To 0th order:

$$m \frac{\partial^2 \xi(t)}{\partial t^2} = eE_0(X) \cos(\omega_{rf}t + \phi)$$

$$\xi(t) = -\frac{eE_0(X)}{m\omega_{rf}^2} \cos(\omega_{rf}t + \phi)$$

Next order:

$$m \frac{\partial^2 X(t)}{\partial t^2} = -\frac{e^2 E_0(x)}{m\omega_{rf}^2} \frac{\partial E_0(X)}{\partial X} \cos^2(\omega_{rf}t + \phi)$$

Average over one period:

$$m \frac{\partial^2 X(t)}{\partial t^2} = -\frac{e^2}{4m\omega_{rf}^2} \frac{\partial E_0^2(X)}{\partial X}$$

Dynamic trapping

$$m \frac{\partial^2 X(t)}{\partial t^2} = - \frac{e^2}{4m\omega_{rf}^2} \frac{\partial E_0^2(X)}{\partial X}$$

For electric quadrupole:

$$E_0(x) = \alpha \left[\frac{V_{rf}}{d} \right] \frac{x}{d}$$

Pseudo-potential:

Sign of e

$$U_{eff}(x) = \left[\frac{\alpha^2 e^2 V_{rf}^2}{4m\omega_{rf} d^4} \right] x^2$$

Harmonic frequency:

$$\omega_{trap} \sim \frac{eV_{rf}}{m\omega_{rf} d^2}$$

Trapping

RF Paul trap

Potential :

$$\Phi = \sum_i \left(\alpha_i + \beta_i V_0 \cos(\omega_{rf} t) \right) X_i^2$$

Solve E.O.M :

$$M \ddot{\vec{X}} = \vec{F} = -e \nabla \Phi$$

$$\left(\text{Mathieu eq: } \frac{d^2 X_i}{d\tau^2} + [a_i + 2q_i \cos(2\tau)] X_i = 0 \quad \right)$$

Stable solution:

$$\omega_{trap} \sim \frac{e V_{RF}}{m \omega_{rf} d^2}$$

d – the distance between the ion and the electrodes

- Drive frequency ~ 20-30 MHz
- RF amplitude ~ 200-300 V
- Secular frequency
- Radial ~ 2-3 MHz –
- Axial ~ 1 MHz –

Weizmann trap.

$\sim 2\text{--}5 \mu\text{m}$

Nitzan Akerman

Scale up?

One (out of many) problem:
isolating one mode of motion for gates

The ion vision: Multiplexed trap array

interconnected multi-trap structure
subtraps completely decoupled

routing of ions by controlling
electrode voltages

Subtrap for different purpose:
Gates, readout, etc.

Other proposals: DeVoe, Phys. Rev. A **58**, 910 (1998) .
Cirac & Zoller, Nature **404**, 579 (2000) .

Multi-zone ion trap

NIST

- Gold on alumina construction
- RF quadrupole realized in two layers
- Six trapping zones
- Both loading and experimental zones
- One narrow separation zone
- Closest electrode ~140 μm from ion

Ion transport

NIST

6-zone alumina/gold trap

(Murray Barrett, John Jost)

- Ions can be moved between traps.
Electrode potentials – varied with time
- Ions can be separated efficiently in sep. zone
Small electrode's – potential raised
- Motion (relatively) fast
Shuttling (adiabatic): – several 10 μs
Separating: few 100 μs –

Surface-electrode traps

Elbows and tee-junctions possible:

Micro-fabricated traps

Allcock; Oxford

Shappert; Georgia Tech

Amini; NIST

Amini *et al.* New J. Phys. 12, 033031 (2010).

Trapped ions on the tabletop

Harmonic oscillator levels

- Doppler cooling. $\langle n \rangle \sim 3 - 20$
- Resolved side band cooling. $\langle n \rangle \sim 0$

Sideband Spectroscopy

Scan the laser frequency •
across the $S \rightarrow D$ transition

Resolved-sideband Cooling

Sideband cooling to the ground state

$$\langle n \rangle < 0.05$$

- $T \approx 2 \mu\text{K}$
- Uncertainty in ion position = ground state extent

$$\sqrt{\frac{\hbar}{2m\omega_{ho}}} = 6\text{nm}$$

Anomalous heating

$$\dot{n} \propto \frac{1}{z_o^{3.5}}$$

- Fluctuating charges
- $f^{1.5}$ noise
- Thermally activated
- Due to monolayer of C on electrodes: gone after Ar⁺ ion cleaning
